*Of course patients should be cautioned against hazardous tasks requiring mental alertness. See overleaf for prescribing information.

8103278

Tranxene® (CLORAZEPATE DIPOTASSIUM) 4306CB

CAPSULES,
SINGLE DOSE TABLETS
Brief Summary

ACTIONS — Pharmacologically, clorazepate dipotassium has the characteristics of the benzodiazepines. It has depressant effects on the central nervous system. The primary metabolite, nordiazepam, quickly appears in the blood stream. The serum half-life is about 2 days. The drug is metabolized in the liver and excreted primarily in the urine. (See CLINICAL PHARMACOLOGY section.)

INDICATIONS — TRANXENE is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

TRANXENE is indicated for the symptomatic relief of acute alcohol withdrawal.

The effectiveness of TRANXENE in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

CONTRAINDICATIONS — TRANXENE is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

WARNINGS — TRANXENE is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on TRANXENE should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since TRANXENE has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, TRANXENE is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence:

Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepate. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.

Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. TRANXENE, a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

TRANXENE should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS — In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Patients on TRANXENE for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS — The side effect most frequently reported was drowsiness. Less commonly reported (in descending order of occurrence) were: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects included insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.

Decrease in systolic blood pressure has been observed.

DOSAGE AND ADMINISTRATION

For the symptomatic relief of anxiety:

TRANXENE is administered orally. The capsules may be given in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 15 to 60 mg. daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a daily dose of 7.5 to 15 mg.

TRANXENE capsules may also be administered as a single dose daily at bedtime; the recommended initial dose is 15 mg. After the initial dose, the response of the patient may require adjustment of subsequent dosage. Lower doses may be indicated in the elderly patient. Drowsiness may occur at the initiation of treatment and with dosage increment.

TRANXENE-SD tablets (22.5 mg.) may be administered as a single dose every 24 hours. This tablet is intended as an alternate dosage form for the convenience of patients stabilized on a dose of 7.5 mg. capsules three times a day. TRANXENE-SD tablets should not be used to initiate therapy.

TRANXENE-SD HALF STRENGTH tablets (11.25 mg.) may be administered as a single dose every 24 hours.

For the symptomatic relief of acute alcohol withdrawal:

Recommended schedule: 1st 24 hours, 30 mg. TRANXENE initially, followed by 30 to 60 mg. in divided doses; 2nd 24 hours, 45 to 90 mg. in divided doses; 3rd 24 hours, 22.5 to 45 mg. in divided doses; 4th day, 15 to 30 mg. in divided doses. Thereafter gradually reduce to 7.5 to 15 mg. daily, and discontinue as soon as condition is stable. Maximum daily dose is 90 mg. Avoid excessive reductions in total drug on successive days.

DRUG INTERACTIONS — If TRANXENE is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that TRANXENE prolongs the sleeping time after hexobarbital or after ethyl alcohol, increases the inhibitory effects of chlorpromazine, but does not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If TRANXENE is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

MANAGEMENT OF OVERDOSAGE — Overdosage is usually manifested by varying degrees of CNS depression ranging from slight sedation to coma. As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

There are no specific antidotes for the benzodiazepines. The treatment of overdosage should consist of the general measures employed in the management of overdosage of any CNS depressant. Gastric evacuation either by the induction of emesis, lavage, or both, should be performed immediately. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though rarely reported, may occur with large overdoses. In such cases the use of agents such as Levophed® (levarterenol) or Aramine® (metaraminol) should be considered.

While reports indicate that individuals have survived overdoses of TRANXENE (clorazepate dipotassium) as high as 450 to 675 mg., these doses are not necessarily an accurate indication of the amount of drug absorbed since the time interval between ingestion and the institution of treatment was not always known. Sedation in varying degrees was the most common physiological manifestation of TRANXENE overdosage. Deep coma when it occurred was usually associated with the ingestion of other drugs in addition to TRANXENE.

CLINICAL PHARMACOLOGY — Studies in healthy men have shown that TRANXENE has depressant effects on the central nervous system. Prolonged administration of single daily doses as high as 120 mg. was without toxic effects. Abrupt cessation of high doses was followed in some patients by nervousness, insomnia, irritability, diarrhea, muscle aches, or memory impairment.

Absorption — Excretion:

After oral administration of TRANXENE, there is essentially no circulating parent drug. Nordiazepam, its primary metabolite, quickly appears in the blood stream. In 2 volunteers given 15 mg. (50 μC) of ^{14}C-TRANXENE, about 80% was recovered in the urine and feces within 10 days. Excretion was primarily in the urine with about 1% excreted per day on day 10.

HOW SUPPLIED — TRANXENE (clorazepate dipotassium) is supplied as capsules in three dosage strengths:

3.75 mg. capsules (gray with white cap) in bottles of 100 (NDC 0074-3417-13) and 500 (NDC 0074-3417-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3417-11).

7.5 mg. capsules (gray with maroon cap) in bottles of 30 (NDC 0074-3418-30), 100 (NDC 0074-3418-13) and 500 (NDC 0074-3418-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3418-11).

15 mg. capsules (all gray) in bottles of 100 (NDC 0074-3419-13) and 500 (NDC 0074-3419-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3419-11).

TRANXENE-SD single dose tablets are supplied in two dosage strengths:

TRANXENE-SD 22.5 mg. tablets (tan-colored) in bottles of 100 (NDC 0074-2997-13).

TRANXENE-SD HALF STRENGTH 11.25 mg. tablets (blue-colored) in bottles of 30 (NDC 0074-2699-30) and 100 (NDC 0074-2699-13).

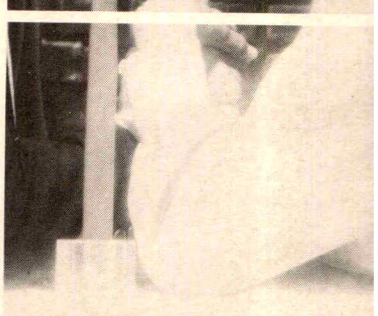
AV/MD, 850 THIRD AVENUE, NEW YORK, N.Y. 10022

Merck Sharp & Dohme announces a new dosage strength

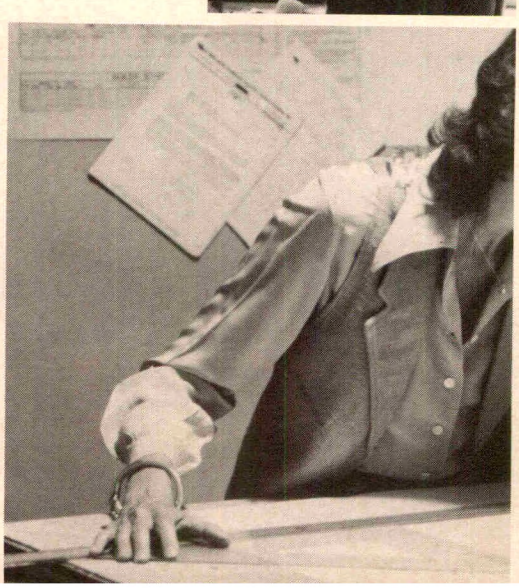
now dual-action Triavil® 4-50

containing 4 mg perphenazine and 50 mg amitriptyline HCl

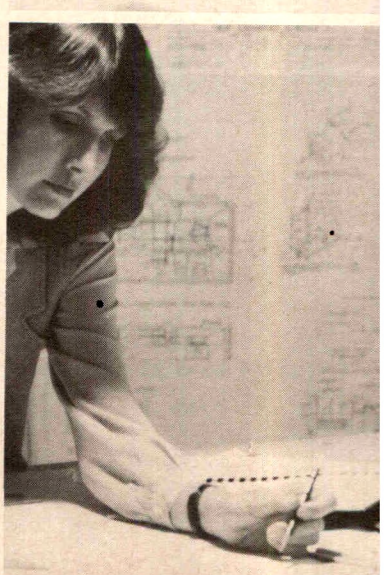
For even more dosage versatility in the treatment of marked agitation with depression



NEW dosage strength—
to simplify therapy
five dosage strengths now available



NEW option: b.i.d. regimen—
to improve compliance
for initiating therapy
Rx TRIAVIL 4-50 b.i.d.



NEW unit-of-use package
bottles of 60 for 30 days of therapy, where appropriate

When TRIAVIL is part of the program, you may anticipate these therapeutic benefits for many patients:

Rapid antianxiety effect
The tranquilizer component can alleviate symptoms of anxiety and agitation within a few days. Hypnotic effects from the tranquilizer component appear to be minimal, particularly in patients permitted to remain active.

Highly effective antidepressant action
The antidepressant component can help relieve symptoms of depression such as poor concentration and feelings of hopelessness as well as early morning awakening; adequate relief of symptoms may take a few weeks or even longer.

...to aid the psychotherapeutic process
Patients often become more accessible and cooperative; symptomatic relief may enable the patient to function more effectively in his daily activities.

Treatment with TRIAVIL—a balanced view:
TRIAVIL is contraindicated in CNS depression from drugs, in the presence of evidence of bone marrow depression, and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. TRIAVIL may impair mental and/or physical abilities required for performance of hazardous tasks such as operating machinery or driving. The drug may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

MSD
MERCK SHARP & DOHME

Please see following page for a brief summary of prescribing information.

For a wide range of patients with marked agitation and depression

dual-action Triavil®

containing perphenazine and amitriptyline HCl

now offers more dosage strengths than any other formulation containing a tranquilizer and an antidepressant

dual-action Triavil®

containing perphenazine and amitriptyline HCl

Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl.
TRIAVIL® 4-50: Each tablet contains
4 mg perphenazine and 50 mg amitriptyline HCl.
TRIAVIL® 4-25: Each tablet contains
4 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl.

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); evidence of bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with TRIAVIL. Therapy should then be initiated cautiously with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given concomitantly with guanethidine or similarly acting compounds since TRIAVIL may block the antihypertensive action of such compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. Dosage of anticonvulsive agents may have to be increased. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time, particularly in high doses. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of some untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides. There is sufficient experimental evidence to conclude that chronic administration of antipsychotic drugs which increase prolactin secretion has the potential to induce mammary neoplasms in rodents under the appropriate conditions. There are recognized differences in the physiological role of prolactin between rodents and humans. Since there are, at present, no adequate epidemiological studies, the relevance to human mammary cancer risk from prolonged exposure to perphenazine and other antipsychotic drugs is not known.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) have been reported and can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw. Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. Fine vermicular movements of the tongue may be an early sign of the syndrome. The full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; other adverse reactions reported with various phenothiazine compounds, but not with perphenazine, include grand mal convulsions, cerebral edema, polyphagia, pigmentary retinopathy, photophobia, skin pigmentation, and failure of ejaculation.

The phenothiazine compounds have produced blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); and liver damage (jaundice, biliary stasis).

Pigmentation of the cornea and lens has been reported to occur after long-term administration of some phenothiazines. Although it has not been reported in patients receiving TRIAVIL, the possibility that it might occur should be considered.

Hypnotic effects, lassitude, muscle weakness, and mild insomnia have also been reported.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs and must be considered when amitriptyline is administered. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; increased intraocular pressure; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

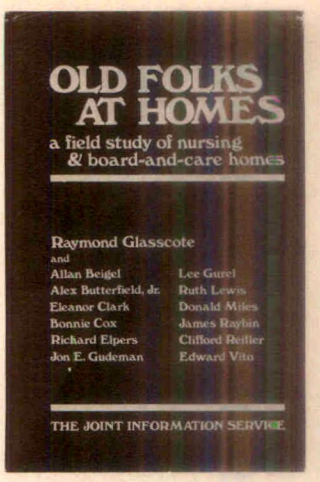
MSD
MERCK SHARP & DOHME

The Joint Information Service of the American Psychiatric Association and the Mental Health Association releases Two New Volumes That

Focus on the Elderly



This carefully documented book reports a field study of ten programs, four in America and six in England and Scandinavia, which serve as practical demonstrations of creative mental health services for the elderly. They include:

- a novel "Neighborhood Family" providing vigorous support to elderly residents of several trailer parks
- a high school for the elderly which sends its students abroad for study trips
- a "Human Development Project" that focuses on responding to the psychological needs of the elderly
- a carefully coordinated system of "respite hospitalization," which promotes the health of the elderly while allowing maximum use of hospital beds and family resources
- a "Lucy Booth," patterned after the Peanuts comic strip, which provides easy access to many kinds of services
- and many other innovative, successful approaches.

Each program is subjected to intensive scrutiny. The resulting document becomes a handbook, and, as well, a forum through which some of the world's most experienced practitioners of "the psychiatry of old age" present their views.

Dr. Wilma Donohue, director of the International Center for Social Gerontology, characterizes this volume as "a masterful job of putting everything in relief . . . the guidelines for action are right here."

190 pages. Casebound. Price $8.50.

Concerned about the very bad reputation that nursing homes have received from many quarters in recent years, the Joint Information Service set up a field study to visit a systematically chosen sample of nursing homes, and board-and-care homes as well, to see to what extent the care of and the quality of life for the patients differed from the geriatrics units of state hospitals. Altogether, sixty nursing homes and 31 board-and-care homes in ten locales were visited, in each case by the senior author accompanied by two mental health professionals.

The teams were surpised to learn that care and quality of life in many of the nursing and board-and-care homes they visited were better—sometimes dramatically better—than that in the mental health facilities and often at lower cost.

This unique publication provides an overview of all facilities visited plus vignettes of approximately half. Federal and state rules and regulations are also expertly synthesized into brief and readable style.

148 pages. Casebound. Price $6.50

American Cancer Society®

We want to cure cancer in your lifetime.

a consideration beyond efficacy alone...

Infrequent akathisia and other disabling extrapyramidal effects...

The rapidly rising readmission rate among discharged psychotic patients is mainly due to noncompliance with antipsychotic drug therapy. And this, in turn, may be largely attributed to disabling extrapyramidal side effects, notably akathisia.[1]

Although extrapyramidal effects are characteristic of antipsychotic agents in general, with Mellaril (thioridazine) such effects are infrequent. Adding an antiparkinsonian agent—which can cause its own side effects—can usually be avoided. Mellaril (thioridazine) is contraindicated in patients with severe hypotensive or hypertensive heart disease.

Extrapyramidal Effects of Selected Antipsychotic Agents*[2]

DRUG	EXTRAPYRAMIDAL EFFECTS
Chlorpromazine	Moderate
Perphenazine	High
Prochlorperazine	High
Fluphenazine	High
Acetophenazine	Moderate
Trifluoperazine	High
Chlorprothixene	Moderate
Thiothixene	Moderate
Haloperidol	High
MELLARIL® (thioridazine)	Low

*Based on antipsychotic dosage ranges

Mellaril® [thioridazine]

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP
CONCENTRATE: 100 mg per ml

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.
Store and dispense Concentrate below 86°F; use tight, amber glass bottle. Just prior to administration, Concentrate may be diluted with distilled water, acidified tap water, or suitable juices; preparation and storage of bulk dilutions is not recommended.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.
It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

THE AMERICAN JOURNAL OF PSYCHIATRY

Psychiatry and the Fiscal Third Party

BY PAUL CHODOFF, M.D.

Third-party payment has profound effects on such areas of psychiatry as confidentiality; diagnosis; the therapeutic relationship; psychiatry's identification with the rest of medicine and the role of nonphysician mental health professionals; psychiatric education; and the availability, type, location, and quality control of treatment. As third-party payment becomes increasingly frequent, psychiatrists will have to come to terms with its good and bad effects in hospitals and community mental health centers as well as in private practice.

SYSTEMS FOR SUPPLYING psychiatric care can be defined and differentiated by the methods which they are funded (1). There are essentially three such methods: direct out-of-pocket payment by the recipient of care to the psychiatrist; payment in whole or in part by a third party, almost always a provider of health insurance otherwise not involved in the treatment; and public funds from federal, state, county, or city sources. Thus, psychiatric care in the Veterans Administration and the military is funded entirely by the federal government. State mental hospitals operate principally with state money but also receive some insurance and out-of-pocket payments. Health maintenance organizations are financed entirely through prepaid insurance, and the community mental health centers depend largely on public funds, although they may receive third-party and out-of-pocket payments.

The private practice of psychiatry today is a system whose payment method appears to be in a state of transition. Replacing direct out-of-pocket payment by the patient (or an interested party) to the psychiatrist is an increasing reliance on insurance funds. An essentially two-party transaction thus is being converted to one involving three parties.

The principal theme of this paper will be an examination of the effects on private practice of a third party operating as a payment agent between the recipient of care and the psychiatrist. Some comparisons will be made between two-party (out-of-pocket) and three-party practice and also between fee-for-service private practice on the one hand and the organized systems of psychiatric care on the other. Just as casting a stone into a still pond has a spreading ripple effect, so the interposition of the fiscal agent between the two directly involved participants has widespread and profound consequences for the psychiatric transaction. Third-party payment not only produces new conditions but also, and possibly even more importantly, makes unavoidable a confrontation with certain aspects of the practice of psychiatry that have not heretofore demanded attention in so urgent and persistent a manner. An analogy might be the increased complexity which results when diadic relationships become triadic in the course of infant-child development.

THE MEDICAL MODEL

One of the previously latent issues that the introduction of third-party payment has brought to the surface is the so-called medical model problem. The "medical model" is a term that is employed widely and generally rather loosely. It has been equated solely with organicity—one is not sick unless he or she has a demonstrable organic lesion. In a broader and more inclusive definition, "sickness" describes a form of deviant behavior with the following characteristics: it is negatively valued by society, it is involuntary—the individual displaying it is not responsible for his or her "sick" behavior—and it falls under the professional purview of physicians (2). Any individual satisfying these criteria assumes what has been called the "sick role" (3) and becomes a "patient." An organic ciol

Dr. Chodoff is Clinical Professor of Psychiatry, George Washington University School of Medicine, Washington, D.C. Address reprint requests to him at 1904 R St., N.W., Washington, D.C. 20009.

ogy for the behavior is often present but is not essential.

The definition of the medical model can provide material for an interesting academic debate with scholastic overtones, but the issue becomes of immense practical importance when the livelihoods of a whole profession are affected by attitudes about this abstract concept. In fact, I submit that possibly the most urgent question facing psychiatry as a profession today is the medical model question—to what extent are psychiatrists physicians and the people they deal with professionally, patients?

How are these questions about the medical model affected by the transition of practitioners from two- to three-party payment? The companies and government programs that provide the benefits for their subscribers, being in the health insurance business, must operate on the basis of some definition of illness even though the definition is likely to be covert rather than clearly formulated. In practice, the model they are familiar with works most easily with such diseases as pneumonia and appendicitis, conditions with medical diagnoses, more or less demonstrable pathology, and obvious degrees of functional disability. It is true that such criteria may be lacking in substantial portions of the caseloads of nonpsychiatric physicians; however, it is their absence in many psychiatric cases that particularly seems to give rise to confusion, uncertainty, and even suspicion in health insurance circles.

Therefore, the cost of long-term psychiatric care, both inpatient and outpatient, is not the only reason that most insurance companies balk at providing full benefits for the patients of psychiatrists. There is also a reluctance to do so because insurance people do not understand how and why certain psychiatric patients can be considered "sick." They complain that they "can't get a handle" on psychiatry for the purpose of planning, projecting, and actuarializing the claims they will be required to pay.

Difficulty in Diagnosis

One specific way in which these medical model uncertainties become manifest is in the transmission of *DSM-II* diagnoses to insurance carriers in connection with claims for psychiatric services. It is accepted that diagnosing illness is a medical function par excellence. Why, then, is there such a furor about submitting psychiatric diagnoses in connection with insurance claims? There are two reasons. First, and very important, is the confidentiality issue, which I will deal with later as one of the consequences of the change from the two- to the three-party payment system. However, I believe that a legitimate fear that confidentiality will be breached in a damaging way is not the only reason for psychiatric reluctance to make and transmit diagnoses. It must be acknowledged that some psychiatric patients, particularly but not exclusively those treated in office practices, simply do not lend themselves very well to the medical diagnostic process. In general, psychiatric patients seen in various settings include a very wide continuum of troubled human beings (4). At the unequivocally "medical" end of this spectrum are individuals with various forms of organic brain disease. Next are the major psychotic disorders, followed successively by the symptomatic neuroses and the personality disorders included and described in *DSM-II*. However, psychiatrists also treat some patients with more or less serious character deformations resulting in persistent maladaptive disturbances that do not conform specifically to the *DSM-II* categories (this is also true, although possibly to a lesser extent, of the broader and more inclusive *DSM-III*). Legitimate differences exist as to where along this continuum the division should be made, but it is clear that the patients at one end comprise a very different population from the "patients" at the other end and that the latter can be included under even an elastic definition of the medical model only with a good deal of Procrustean manipulation. Thus, even leaving out considerations of confidentiality, the difficulty in finding appropriate medical diagnoses for patients who fall at the nonmedical end of this spectrum accounts for some of the reluctance of psychiatrists to transmit diagnoses to insurance companies who are reimbursing their patients.

Psychiatrists' Reactions

Since, however, the diagnostic procedure is necessary for reimbursement, psychiatrists must conform or run the risk of losing their patients. They cannot avoid dealing with the ambiguous aspects of their profession's medical identification. Like most people faced with ambiguity, they may react with anxiety and defensiveness; thus, some of the resentment felt and expressed by psychiatrists toward the insurance carriers may contain elements of projection. I would even suggest that the emphasis on breaches of confidentiality as a barrier to transmission of information, when present to an exaggerated degree, may be a rationalization for the uneasiness of a psychiatrist confronted with the need to make a medical diagnosis in cases in which the medical diagnostic procedure is not particularly applicable. Practically speaking, when he or she is unwilling to make an accurate diagnosis because of considerations of confidentiality or is unable to do so for the reasons described above, a psychiatrist is likely to take refuge in writing bland diagnoses such as anxiety neurosis or depressive neurosis. This device satisfies formal requirements and is usually generally descriptive of patients' conditions. Such diagnoses are unlikely to have an adverse effect on the therapeutic relationship or to damage patients should they be revealed. However, in the long run, this practice can have only negative effects both on the status of psychiatry as a discipline with at least some scientific aspirations and on the attitudes of the insurance carriers, whose suspicions that they may be paying not for medical illnesses but for self-improvement or education will be encouraged. Furthermore, the delicate fabric of the psychotherapeutic relationship, which depends on the honesty and integrity of the therapist, may be damaged in

the atmosphere of collusion between the participants in making such diagnoses only to secure reimbursement.

The situation I am describing is by no means the rule in psychiatric practice but, rather, is one that applies particularly to office psychiatrists engaged primarily in psychotherapy and then only with a segment of their patients. Those psychiatrists who deal with a more clearly medical population may be concerned about breaches of confidentiality with reference to the insurance requirements, but they will usually have no serious difficulty in making diagnoses. Thus, this insurance requirement may be promoting a potential schism in the profession of psychiatry between the "physicians" and the "psychotherapists" since it is the latter whose medical identification is most threatened. It is also clear that these problems are not present in two-party out-of-pocket private practice where payment does not depend on the furnishing of a medical diagnosis to someone other than the participants in the therapeutic transaction. Furthermore, they are much less obvious in the salaried, organized systems for providing psychiatric care. In these—community mental health centers, the military, the VA, and state hospitals—the funding agency is much less likely to key payment to the demonstration of the existence of a distinctly medical illness. The model of social distress or societal disequilibrium may provide an entrée as acceptable to these funding agencies as a "medical" disability (1).

An interesting by-product of the influences I have described is the tendency of individual psychiatrists and of psychiatric organizations to replace a rather casual attitude toward organized medicine with a firmer reidentification and involvement with it. Clearly, when psychiatrists mend their medical fences and reassert their identities as physicians, they are partially motivated by their need to have the services they render included among the benefits dispensed by health insurance plans and future national health insurance programs. Furthermore, the tremendously increased involvement by psychiatric and psychoanalytic organizations in guild and economic issues undoubtedly stems from the same cause.

RELATIONSHIPS WITH OTHER MENTAL HEALTH PROFESSIONALS

Another important consequence of the introduction of insurance funding into psychiatric practice is the uncovering and accentuation of the competitive aspects of the relationship between some psychiatrists and members of other mental health professions (principally but not exclusively clinical psychologists). Like the medical model problem (to which it is certainly related), such competition has always been at least potentially present. Although there are already rumblings that the dispute about who is qualified to treat mental and emotional disorders is moving even into the hospital setting, the chief locus of concern about this issue has been among private practitioners of psychotherapy. Although the question of what kind of training—medical or other—qualifies one as a psychotherapist involves major unresolved substantive issues, there is little doubt that economic considerations also play a significant role (5).

The extension of health insurance coverage has considerably increased the pool of individuals now able to take advantage of the services of private practitioners for psychotherapeutic treatment and thus has created competitive tensions among these practitioners. In this competition, psychiatrists, by virtue of being physicians, are in the favored position to secure health insurance payments for their patients. As noted above, this advantage is motivating psychiatrists to emphasize that they are physicians. At the same time it is also motivating other mental health professionals to assert with some success their right to receive direct reimbursement for psychotherapy in spite of the fact that they have not been medically trained. They may in fact be theoretically uncomfortable with the medical model to which they have to pay at least lip service in order to come under health insurance aegis. In addition, the fact that nonphysicians contend that they are qualified to offer the same services as psychiatrists sharpens the debate over whether this form of treatment is medical and whether it should be funded through health insurance. Pandora's box may be opening here, since the future may bring similar pressures to receive insurance payments from psychotherapists with increasingly diverse (including nonprofessional) training backgrounds.

This issue may exert a divisive influence not only between psychiatrists and mental health professionals but within the psychiatric profession itself, since the strains I have described above apply almost exclusively to those psychiatrists who practice privately and independently and who have little collaborative contact with psychologists or social workers. Academic and institutionally based psychiatrists, on the other hand, must deal every day with colleagues in these and other mental health professions. Thus, they are much more strongly motivated than office practitioners to accommodate the latter group. Furthermore, since these institutional psychiatrists receive their income through salaries rather than in the essentially entrepreneurial manner of private practitioners, they are not so likely to experience the activities of mental health professionals as economically competitive.

HOSPITAL PRACTICE

Up to this point I have been dealing with third-party payment effects principally as they apply to outpatient, predominantly psychotherapeutic practices. However, there are also important consequences for psychiatric practice in hospitals. Since insurance programs pay more readily for inpatient than outpatient

medical services, there may be some tendency in psychiatry (although probably not so much as with other medical specialties) for patients to be admitted for workups and treatment regimes that might otherwise be handled on an outpatient basis. Also, day hospitals that offer an alternative to hospitalization are hampered in their efforts to compete with the latter by reason of less favorable insurance coverage. In general, however, the coverage available for inpatient units in general hospitals encourages acute care in such institutions and cuts down on the necessity for municipal or state mental hospitalization. This is not an insignificant factor in the marked reduction in the populations of such hospitals and can be considered to play a role in discouraging the development of chronicity.

The availability of insurance coverage also promotes the successful development of certain specialized psychiatric hospitals that provide acute and intermediate care essentially through the team approach. These hospitals, while often innovative in their program, are likely to emphasize services that will qualify for reimbursement. In accordance with the old adage that he who pays the piper calls the tune, it is becoming clear that the carriers are demonstrating an increasing power to control the kinds of services offered in institutions dependent for their survival on the income derived from insurance sources.

RECIPIENTS AND PROVIDERS AND TREATMENT PLANNING

The most clearly beneficial effect of widespread insurance coverage for psychiatric conditions is to open up the private practice option to a socioeconomic population for whom it previously would have been unavailable. Prospective patients are no longer dependent solely on charity or on publicly financed systems. Because in our culture private practice is highly valued and attracts effective and well-trained practitioners, there is at least theoretically a resultant overall improvement in the care available to a wider stratum of the population. This broadening of the socioeconomic mix of patients may also make it possible for certain theories of psychopathology and personality development to be less culturebound than they were, for instance, when Freud was basing his ideas on a rather narrow sample of upper-middle-class Viennese.

In areas with good insurance coverage for outpatient private practitioner services, there has been a considerable increase in the demand for them. It is not clear whether this indicates the existence of a previously unmet need or whether the ancillary payment method may also be encouraging a broadening of the concept of what sorts of personal distress are indications for psychotherapy in our society. At any rate, it has been estimated that there are 31.6 psychiatrists per 100,000 population in the Washington, D.C., area, with its excellent third-party program for federal employees, a figure equalled only by New York City (32.8 per 100,000) and in contrast to an average of less than 10 per 100,000 in the rest of the country (6). This is dramatic evidence of the efficacy of insurance programs in increasing the supply of psychiatrists (and also of other mental health professionals). In the Washington, D.C., area, where the Federal Employees Health Benefits program is a very important source of payment for most practitioners, an incidental effect has been a tendency for the fee psychotherapists receive to be standardized at the level for which the insurance carrier will make an 80% reimbursement. Consequently (and rather unexpectedly) it is possible for the incomes of neophyte therapists quickly to reach equality with those whose experience is considerably greater. This occurs, of course, only if the field does not become so overcrowded that entrants into practice find difficulty filling their schedules.

Besides increasing the supply of both practitioners and patients, the insurance money also influences the modalities, intensity, duration, and goals of treatment planning. Thus, the decision whether to offer long-term intensive or short-term return-to-function psychotherapy to a patient obviously depends on many factors but certainly includes as an important consideration the state of the prospective patient's finances. The knowledge that insurance help can be counted on frees the therapist to exercise his or her best clinical judgment about the treatment modality best suited to the case. On the other hand, the availability of funds has the potential for encouraging malutilization of both outpatient and inpatient treatment. Thus, a hospital stay may be terminated not solely for clinical reasons but because the insurance entitlement has run out. The somewhat fuzzy indications for certain psychotherapeutic modalities may be stretched because insurance coverage is available and because the therapist prefers these modalities. The same may be said of the proliferation of psychotherapy groups, sometimes without adequate patient selection or clinical indications. Again we note the contrast with two-party private practice where lack of out-of-pocket funds may limit treatment options but also may curtail such looseness. With the salaried systems for providing psychiatric care, financial incentives to prolong treatment do not exist. However, in these systems, particularly the HMOs, the funding method may have the opposite effect of encouraging unduly short-term and limited treatment rather than the more intensive but more expensive methods that may be indicated in some cases.

PSYCHIATRIC EDUCATION

As with other medical specialties, the trend toward vastly increased health insurance coverage among the general population has affected undergraduate and resident education in psychiatry because charity patients are no longer as available to students and residents for teaching purposes. Also, the assurance required by the insurance carriers that the "specialists"

whom they are paying for their services have proper credentials adds motivation for taking national Board examinations. Such third-party pressures, combined with the movement for continuing education, are also generating an interest in various credentialing mechanisms among subspecialties. For instance, the major psychoanalytic organizations have already moved toward specialty certification in order to establish a mechanism that would indicate which practitioners are qualified and thus eligible to have their patients receive benefits.

PEER REVIEW AND STANDARDS

Review and monitoring of the professional activities of their colleagues by peers within the specialties of medicine clearly seems to be an idea whose time has come. In psychiatry today we see a rich ferment that includes both concurrent and retrospective review of in-hospital and outpatient treatment practices. The American Psychiatric Association has moved far in this field; in fact, when questions are raised about including full coverage of psychiatric treatment under the aegis of insurance and national health insurance, APA presents its panoply of peer review activities with the claim that peer review in the hands of the profession itself will be effective not only in eliminating abuses but also in controlling costs.

Another important reason for the current interest in peer review, besides these economic pressures, is the public enthusiasm for and adaptation of the ethic of accountability. Accountability requires that whoever dispenses goods or services to the public must be able to assure the consumer that the product is what it is stated to be, that it is being offered in good faith, and that the consumer has recourse for complaints and questions. The burgeoning consumer movement has been adopted and encouraged by third-party insurance funders for their own purposes, which are to protect their subscribers from abuse, to keep their costs down so that they can successfully compete with other carriers, and to make projections and plans on the basis of reasonably consistent actuarial data. These aims have been accepted as legitimate by organized psychiatry, which has offered its cooperation by instituting peer review. Incidentally, the tendency for psychiatric peer review to be conducted under the aegis of medical societies rather than independently is additional evidence of the reidentification of psychiatry with the rest of medicine.

How effective psychiatrists will be in monitoring their own profession through peer review remains to be seen. Skepticism has been expressed (7) about whether it is possible for the members of any profession to forego their own guild and economic interests sufficiently to protect the public. The stakes are very high in this endeavor since failure to convince the public and the third parties that these efforts at self-control are effective is likely to lead to the introduction of extraprofessional monitoring with all the threat of loss of professional autonomy this would pose. I am inclined to question whether peer review is an effective cost control mechanism, but I believe that it can be a potent means of dealing with abuses and will patterns of malutilization of certain services (8).

I mentioned previously that insurance pressures generally are felt more strongly in private practice than in the organized, salaried systems. This is a matter of peer review. A mechanism to account for whether subscriber money is being spent properly and prudently appears to be of greater concern to insurance funders than to the funders for the military and the VA. In these systems the relationship between the source of funds and the providers of care is not nearly so direct as that between insurance carriers and private practitioners of psychiatry. Consequently, VA and military psychiatrists are not being influenced to establish peer review committees by these economic considerations, although they may do so for other reasons (9).

Quality control measures also become a source of tension between third-party payers and practitioners in the establishment of standards for various aspects of psychiatric treatment. In order to process claims and to project and control their operations in general, the carriers seek relatively simple, hard and fast criteria for such treatment concerns as length of stay in hospital, average duration of psychotherapeutic treatment for various diagnostic entities, the usual number of members in a psychotherapeutic group, the optimum number of electric shock treatments, etc. Specific answers to these and many other questions are sought so that they can be translated into guidelines to provide nonprofessional claims review personnel with an easy and efficient way of deciding whether a claim should be paid immediately or held back for further scrutiny.

The nature of the examples I have given will immediately arouse discomfort and frustration in psychiatrists, most of whom will agree that the diagnostic categories and treatment modalities of their profession lend themselves poorly to rigid rules. This conflict between insurance carrier needs for standards and the reluctance and inability of psychiatrists to supply them is responsible for some of the antagonism that exists between the two groups. It affords a sobering example of the power that their financial control gives to the carriers to shape and influence the kinds of services that can be offered to patients. It puts psychiatrists in a dilemma between the wish to operate free of such external and nonprofessional constraints and the knowledge that they cannot do this and also protect their patients' ability to receive reimbursement.

In the course of discussion about the reimbursement of certain treatments the question is sometimes raised by third parties (insurance or governmental) about evidence of their effectiveness. This confronts psychiatrists, in an embarrassing way, with the paucity of reliable outcome studies, particularly with regard to the psychotherapeutic modalities. Among the reasons for trying to remedy the present unsatisfactory state of re-

search in this area is the need to be able to lay before third-party carriers and national health insurance planners evidence that psychotherapy in the hands of competent therapists is a valid mode of treatment.

TREATMENT RELATIONSHIPS

That someone else is (as it were) peering at the treatment transaction, no matter how distant the vision or dark the glass, is bound to influence the relationship between the two participants. This is true whatever the diagnosis or the modality, but it is likely to be more troublesome and have potentially graver consequences for those forms of psychotherapy in which scrutiny of the relationship itself is a therapeutic instrument.

Confidentiality

Just as the wider availability of treatment relatively free of financial constraints is the most distinct advantage of insurance coverage, so its greatest disadvantage is the inevitable intrusion of the payer into the therapeutic relationship. Granted the legitimacy of the third party's requirements for certain information to process claims and to protect the financial interests of other subscribers, this need is still felt as a wrench. It interferes with the therapeutic benefit derived from the assurance to the patient that anything he or she says will be absolutely inviolate. There are bound to be disturbing questions about possible misuse of the information transmitted. Thus, psychiatrists will disgorge the information required to justify payment of claims with a degree of reluctance that varies according to the amount requested and the sensitivity of the information.

It is in this matter of confidentiality that one must acknowledge the inestimable advantage of two-party treatment, where, in an increasingly impersonal and bureaucratized culture, there still exists an oasis of assurance that one's secrets will be safe.

A sobering instance of the widespread consequences of the breaching of confidentiality in connection with insurance reimbursement occurred in the Washington, D.C., area when a new mental health report form, which required a great deal more information in regard to federal employee subscribers, was introduced by Blue Cross/Blue Shield. Especially since most psychotherapists felt that they had to reveal the form and their answers to its questions to their patients, a whole gamut of complicated reactions ensued, ranging from refusal of some patients to start treatment and disruption or serious interruption of treatment in a few instances to apparently neutral responses and even, occasionally, to effects that could be described as beneficial. The form generated a very marked negative reaction among the psychiatrists involved, most of whom indignantly regarded it as a kind of latterday plague; their efforts (plus the threat of legal intervention) led to the withdrawal of the form. Whether or not all the fears expressed were entirely realistic, the episode served to demonstrate that insurance carriers do deal differently with psychiatrists than other medical specialists. It also highlights the resentment among the psychiatric community at giving up its cherished autonomy and conforming to the requirements of a fiscal third party.

Allegiance

Although a psychiatrist cannot ensure a patient the absolute confidentiality that exists in two-party transactions, the psychiatrist whose patient accepts insurance reimbursement is unlikely to have serious internal conflicts about whose interests he or she is serving. The psychiatrist will certainly opt for the interests of the patient rather than those of the payer in any conflict between the two in which he or she has a choice. In private practice in general, whether two or three parties are involved, there is not likely to be the kind of conflict between the interests of the patient and the psychiatrist which may occur in salaried organized systems—for instance, in the military, where the importance of the mission may supersede the needs of the individual patient in treatment (1).

Transference-Countertransference Relationships

How does the presence of the third party affect those subtle and shifting currents in the relationship between the two participants that play so important a role in insight-oriented psychotherapy and psychoanalysis? Does it constitute an interference so grave as to hamper seriously the overall effectiveness of such treatment? As with other questions concerning psychotherapy, we do not have the benefit of satisfactory outcome studies but must rely on overall impressions, anecdotal material, and individual case reports. On some matters, there appears to be agreement. It seems clear that in some cases the limitation of the patient's own financial responsibility for treatment encourages acting out through missing appointments with a frequency that would be unlikely if his or her own pocketbook were more seriously affected. This phenomenon, incidentally, raises the question of whether rules about charging fees for missed hours should be altered when payment comes not exclusively from the patient but ultimately from other subscribers to an insurance plan. Some therapists hold that the situation is unchanged by the source of payment since their relationship is solely with the patient. Other therapists, however, are troubled and see the situation in terms of an ethical issue not present in two-party contracts. Also, as with the diagnostic practices previously described, it is possible that an atmosphere of collusion with the patient that is inimical to treatment might develop when such instances are frequent.

Although some influence on other transference-countertransference manifestations would be expected because of the third-party intrusion in such an important aspect of the therapeutic relationship as payment, the nature of this effect has not been explored thor-

oughly. There are reports about problems arising from insurance payment, such as the encouragement of a feeling of omnipotence in the patient who is getting treatment for little or no cost (9). Whether such problems are frequent is not clear; it is possible, of course, that they could be used productively as grist for the psychotherapeutic mill. Psychoanalysts who use the treatment model of the resolution of the transference neurosis through interpretation might be concerned that patient-therapist collaboration in dealing with the third party could interfere with analytic neutrality by emphasizing the real aspects of the analyst. Also, if the analyst adheres to the "sacrificial fee" theory that successful treatment depends on regular, somewhat painful disgorgements of money from the patient, problems might be anticipated in cases where insurance has made payment easier (10). In response to these caveats, it can be stated only that no firm evidence has been adduced which suggests that treatment results have been substantially downgraded by these potential obstacles to transference-countertransference maturation (11).

DISCUSSION

The introduction of a third-party funding agent into the treatment transaction between patient and psychiatrist has been associated with important and unexpected consequences for many aspects of the practice of psychiatry. Some of these consequences are unequivocally positive, notably the greater availability of the private practice option and the freeing of treatment planning from financial constraints. There have also been unequivocally unfavorable effects—the breaching of confidentiality in the treatment relationship, a tendency toward mandating types of treatment by funding agents who are primarily concerned with cost control, and an increased amount of record-keeping and bureaucratic wrangling. Other consequences of the third-party influence are less easy to characterize; their effect varies depending on point of view or usage.

The third-party impact has also brought to the surface with fresh urgency certain questions about the extent to which psychiatrists can properly wear the mantle of physicians. This has created tension between psychiatric practitioners and other mental health professionals. It has also augmented a potential for conflict between psychiatrists whose chief or only treatment modality is psychotherapy and those who have more varied practices and between psychiatrists who earn their living through fees for service and those whose income is derived from salaries within organized systems of psychiatric care.

Because insurance payment for psychiatric services has had such mixed effects, it should not be surprising that the reaction of those psychiatrists whose practices have been heavily influenced by insurance payment has likewise been a mixture of satisfaction, irritation, and uneasiness. The relative freedom from financial constraints in treating patients has been a ... the threat to professional autonomy from ... agencies uninvolved in treatment who appear to view psychiatrists with suspicion and to treat them differently from other physicians.

However, no matter whether the effects ... bad, or indifferent and no matter what the ... of reluctance and acceptance with which they are greeted, there seems to be little question that payment for psychiatric services through a third-party intermediary is bound to play an increasingly ... role. This is true not only for private practice as ... been discussed here, but also for some of the ... systems for supplying psychiatric care, such as community mental health centers and state hospitals. It is probable that sooner or later all psychiatric services in the private sector will be paid for largely through some combination of commercial insurance and national health insurance programs. Thus, unless we take the somewhat idiosyncratic course of withdrawing from such a system entirely in order to preserve two-party values, private practitioners of psychiatry will have to come to terms with the advantages and disadvantages, problems, questions, ambiguities, and ironies resulting from this change in the payment method. The ... of organized psychiatry has reacted to insurance pressures with endless conferences, plans, proposals, ... negotiations, out of which has come the establishment of peer review mechanisms. These responses have thus far been largely on an ad hoc basis. I believe that the time for our profession to take an objective look at the many implications of the changes resulting from the new payment methods so that it can formulate policies that will be reasoned and comprehensive.

On Editing the *Journal*: *Ave Atque Vale*

BY FRANCIS J. BRACELAND, M.D.

Dr. Braceland discusses his 13-year tenure (1965–1978) as Editor of the American Journal of Psychiatry, *noting that he took office during a period of social turmoil that in many ways resembled the decade of the* Journal*'s founding 134 years ago. He describes the advantages and disadvantages of the peer review system he introduced to the* Journal *and states that this approach is essential in a time of ultra-specialization. He reviews the crafts of editing and writing for medical journals, both of which are brightened by clarity and brevity. As to the future of medical journals, he considers reports of their demise premature, while acknowledging the problems they face. Dr. Braceland briefly considered a "rocking chair" approach to his retirement from the Editorship, but the Editor Emeritus will instead continue to provide whatever assistance he can to his colleagues.*

I HAVE BEEN ASKED by the Program Committee to discuss my involvement with the *American Journal of Psychiatry*, which I have had the honor of editing for the past 13 years. I was asked also, if possible, to predict its future, as well as the future of medical journals in general. To carry out this mission, I must first ask your indulgence as I glance back a bit, for when I became the *Journal*'s 9th editor it was already 121 years old and had remained alive through times of war, famine, and pestilence. As I discuss this broad span of years, you must realize that unlike the scholarly mandarin I cannot paint them delicately with an exquisite Chinese brush; my canvas must be broad and my brush wide.

Like many things and people later destined to become great, the *Journal* had a modest beginning. Its birthplace was the Utica Lunatic Asylum, the time was July 1844, and its given name was *The American Journal of Insanity*. None of this sounds very promising, but in its favor was the fact that its sire was Amariah Brigham, a gracious, capable physician, a scholar, a teacher, and a dedicated man.

The decade in which he founded the *Journal* was later to become known as the "Fabulous Forties." The whole nation was awakening and astir; the crude conditions of pioneer life were lessening on the Eastern Seaboard, and there was leisure enough to think of plans for human betterment. Schools, academies, hospitals, and libraries were being opened, and several hospitals for the insane were under construction.

We are justified in looking at this period, for neither institutions nor publications can exist in a vacuum; all are influenced by the social, political, and economic currents that swell around them. The period is best described by Meade Minnigerode, and excerpts from his book, *The Fabulous Forties 1840–1850* (1), give us some idea of the incredible happenings in those times. Speaking of the decade in general Minnigerode said it was

> an unfinished, unstabilized company taking part in a national pageant which there had been no time to rehearse. . . . the apotheosis of banality. . . . A time when females were treated with utmost courtesy and very slight consideration. An indecent dance, the polka, was coming in to complete the demoralization of the younger set. Tight lacing was being blamed as a cause of insanity. . . .

An unbelievably large number of people were enthusiastically awaiting the end of the world on April 23, 1843, a date arrived at by the biblical computations of an itinerant preacher named Miller. Millerites were filling the mental hospitals on the East Coast and ascension robes were selling like hotcakes. Brigham later said that numerous suicides were caused by Millerism and that thousands had their health impaired to such a degree as to unfit them for life in the future.

This was the milieu in which the *Journal* first saw the light of day. Brigham had been drawn to Utica by the enthusiastic directors of the institution then under construction. They assured him it would be an institution second to none, and this appealed to him. A first-class alienist who had been the third superintendent of the Hartford Retreat, he was also a prodigious worker, and he sought every opportunity to educate the public in the intricacies of mental disorders, welcoming interested individuals and teaching those who were well disposed. His restless energy soon took a more important turn; he decided to found a journal.

On May 18, 1844, Brigham wrote to Pliny Earle, Physician to New York's Bloomingdale Asylum, as follows: "I am about starting an *American Journal of Insanity*, quarterly, Octavo, ninety-six pages edited by officers of the Asylum" (2). Two months later the

Revised version of a special lecture presented at the 131st annual meeting of the American Psychiatric Association, Atlanta, Ga., May 8–12, 1978.

Dr. Braceland is Editor Emeritus of the *Journal*, Past President of the American Psychiatric Association (1956–1957), Emeritus Professor of Clinical Psychiatry, Yale University, and Senior Consultant, Institute of Living, 200 Retreat Ave., Hartford, Conn. 06106.

Journal appeared, the first publication of its kind in the English language. Most of the articles were written by Brigham himself. In order to make the publication widely available the price was kept at $1.00 per annum. It was printed and paid for by Brigham alone, and he continued to be its main source of articles. It is of historical interest that in the same year three other psychiatric journals were launched—one English, one German, and one French—and all three are in some form still extant.

The new *Journal* served to keep the few alienists, who lived in widely scattered areas, in touch with one another at a time when the field of psychiatry was practically a wilderness. There was a need for communication that the *Journal* fulfilled. Also, it was undoubtedly a factor in the formation of the Association of Medical Superintendents of American Institutions for the Insane in October 1844, four months after the *Journal* was founded.

The *Journal* proved to be a prodigious task, and Brigham, never robust, was often temporarily disabled by illness. His letters referred frequently to his health, and in 1846 he wrote and asked Pliny Earle to take over, noting, "I am getting old and averse to labor and cannot take charge of the *Journal* another year." At that time he was 48 years old. He carried on, however, until September 8, 1949, when he died at the age of 51 of an attack of dysentery.

Although it is tempting to trace the *Journal*'s further history, I must endeavor to be brief. I should, however, mention the fourth Editor, G. Alden Blumer, who served from 1886 to 1894. It was his unpleasant duty to dispose of the *Journal*, which was still the property of the Utica State Institution and was coveted by the New York State politicians. Fortunately for all, the American Medico-Psychological Association (the name the lineal descendants of our founding fathers had taken) bought the *Journal* for $944.50. Dr. Richard Dewey became Editor and in 1894 the *Journal* was moved to Chicago.

The *Journal* had several additional Editors, all of them interesting and worthy of note, but we have time only to mention one of them, Clarence B. Farrar, the 8th editor. A distinguished, cultured gentleman, Dr. Farrar had been Editor of the *Journal* for 33 years and had run the *Journal* from Toronto when, in 1964, the Council of the American Psychiatric Association decided to consolidate all of its offices and centralize its operations in Washington. Dr. Farrar retired in July 1965.

Dr. Farrar had been Editor over an incredibly important period in history. It covered the Great Depression, pre-war build-up, World War II, and all of the political dislocations of that holocaust. His tenure also saw the beginnings of the greatest recorded advances in psychiatric therapy, including the start of the modern physical therapies and the appearance of the new psychopharmacologic agents. His was a hard act to follow.

A search committee was formed under the chairmanship of Howard P. Rome and the hunt [illegible] Editor was on. There were few applicants [illegible] present incumbent was invited to undertake the task. He accepted even though he knew that the Editor's job was not the best way to make friends. He [illegible] that if one were ever to find a popular editor he would be neither sitting nor standing—he would [illegible] down surrounded with flowers.

The new Editor met with the Council and [illegible] carte blanche in all editorial matters and [illegible] only that the *Journal* was the organization's official organ and that all aspects of the discipline merited consideration. Modest space was found for the *Journal* [illegible] in the Washington headquarters, and by a great stroke of good fortune, Ms. Evelyn Myers, who had editorial experience at the National Institute of Mental Health and elsewhere, was made Managing Editor. She proved to be a "gem of purest ray serene." Nearly I began to worry about the situation facing us. We were not to become "official" until July 1, 1965, and were expected to get out a July issue! This was [illegible] for neophytes, but, fortunately, neither of us realized the enormity of the task before us.

I will pass over quickly the unpleasant things that had to be faced first, namely, returning a number of previously accepted manuscripts that were unacceptable and notifying the distinguished Editorial Board, who had served faithfully for many years, that a new Board would be appointed.

In some fashion not yet understood, the July issue appeared on time. Dr. Farrar wrote me [illegible] hand a note that is my proudest possession and he said he did not believe it could be done. However it was; it looked good and it was on time.

The early issues, without our quite realizing it, gave evidence that the *Journal* was indeed under new management and was "open." In the first and second issues there were articles on psychoanalysis, a subject that had not appeared often in earlier issues. There was also a disquisition by Mike Gorman in which he gave everybody hell all around in an article entitled "Psychiatry and the Public Policy." One sentence, addressed to all psychiatrists, gives an idea of the paper's general tenor: "You can no longer hide in the isolation comfort of your private offices appropriately furnished with an overstuffed couch and a picture of Freud visiting Worcester in 1909."

If there was any doubt that the *Journal* was under new direction, it was now dispelled. Gorman [illegible] repeated the observation of the Angel Gabriel in Connolly's *Green Pastures*: "Everything is all down is coming loose." He was right, for we began our term of office in a period roughly comparable to the Fabulous Forties. The nation was again astir: a [illegible] war was going on, drug use was widespread, "flower children" were running away from home, and college campuses were in turmoil.

Young folks let it be known they were going to take over a tired old world and show those over 30 how to eliminate poverty, racism, prejudice and ev[illegible]

in general. A small irresponsible segment took over universities, presented their nonnegotiable demands, occupied the dean's office, smoked his cigars, Xeroxed his papers, and wrote home for money on his stationery. The virus of discontent spread to medical schools, and Arnold Mandell, a first-class teacher, later wrote,

> Increasingly, bright students, with good academic records, are refusing to accept the challenge of describing character in terms of the dynamics of personality; they tell me that such balanced, lyrical efforts are the masturbatory activity of the passive during this time of social change. (3, p. 529)

The delusional systems of this period were not as tightly reasoned as the Millerism of the 1840s, but they were reinforced in some cases by hallucinogenic drugs, and it all seemed like a bit of a throwback to the time when the *Journal* was born.

There were editorials by two distinguished colleagues in our first issue. Dana Farnsworth wrote about unrest in our colleges. Francis Gerty wrote of the Silver Pitcher, a token of office given originally by a grateful Association to Dr. Dewey and later by his daughter to Dr. Gerty to be passed from Editor to Editor. In the same pages, I wrote an appreciation of the retiring Editorial Board and solicited help from all and sundry in my new job as Editor. Editorials became scarcer as the years went by, not because the Editor was modest or mute but because the *Journal* was soon inundated with manuscripts. There is an old saying that when you are up to your nether end in alligators, it's not the time nor the place to teach the children to swim. Well, we were up to there in manuscripts, and there was no space to spare for the Editor's musings.

BEING PAID WHILE LEARNING

What have we learned through the years? Too much to detail here, and frequently we learned through trial and error. Early on we opted for the referee system, i.e., sending our manuscripts out for peer review. We felt that this was the fairest and the wisest course and we firmly believe in it now. In this procedure, we joined with many other specialty journals, and we agree wholeheartedly with Franz J. Ingelfinger, former Editor of the *New England Journal of Medicine* and the most outstanding contemporary American medical editor, who said,

> Editors who depend on referees to differentiate that which is publishable from that which is not, some would argue are a pusilanimous lot. If they do print an article which turns sour the mishap can be blamed on anonymous reviewers. Editors of course reject this mean spirited charge. But there is no doubt that the average editor, confronted by the products of today's rarified research, lacks the confidence to go it alone. He needs the help of the ultraspecialists to judge the ultraspecial articles so that his journal will print the best of what is submitted and will disseminate material that has the imprimatur of authority. (4, p. 686)

We are fully aware of the system's defects, which include some inadequate reviews, bias on the part of an occasional referee, and unrealistic expectations on the part of the Editor. The costs, time, and effort involved in this system are enormous. Also, there is the possibility of violation of confidence and even the occasional suppression of a novel advance. One study showed that concurrence between two referees shown the same paper was only moderately better than chance, but as yet we know of no better way to operate. On occasion, we have sent the same paper to three, four, or more reviewers, particularly if the subject is controversial. In some cases, when these various opinions from experts have led to a rejection, we later see the paper in another journal.

Unfortunately, there are times when referees fail to view the manuscript fairly or objectively. Some academic groups hold tightly to certain ideas or methods and believe that anything written outside of their boundaries is ipso facto wrong. Occasionally authors ask us not to send their paper to a certain well-known group. This puts the editor in a bit of a quandary, particularly if this group contains a number of the known experts in the subject. Not possessed of the wisdom of Solomon, the Editor searches his roster for the wisest person available to get his advice; he often discusses such problems with members of the Editorial Board.

There are many other problems with the referee system. Some referees hold papers for an unconscionably long time, requiring numerous communications from the editorial office, while we attempt to sooth the justifiably ruffled feathers of the author. Some prospective referees never do answer us. However, as far as we can determine, the referee system in an operation as large as ours is "the only game in town."

Occasionally there have been objections from different groups of our readers about our accepting drug advertisements. Brush fires on the subject are lighted in various sections of the country at intervals. This same problem plagues other journals. Let us turn to Ingelfinger, for we are again in complete agreement with him. After asking what would happen if the *New England Journal* gave up drug advertising, he appended another question: "Would such a solitary, perhaps idealistic, gesture improve either the quality of patient care or the character of the *Journal*?" He answers: "The intensity of the 'no' I hear exceeds that of a sonic boom." He elaborated on his statement:

> Without pharmaceutical advertising, its [the *NEJM*] subscription price would increase about $25 per year. The suggestion that other advertising be sought lacks substance, for enterprises selling to a general market see no reason for placing advertisements in a medium read by only one restricted segment of that market. Similarly fanciful is the cry, "Price does not matter—doctors can pay!" Of course they can, but will they? . . . In spite of its

exceptional qualities, the *Journal* would be threatened by an ominous prognosis. Circulation would drop, and the subscription price would correspondingly rise even more. In other words, the *Journal* might well achieve a moral but pyrrhic victory, for it would be as pure and free of taint as a corpse. (5, p. 529)

We read also in that same dissertation (p. 528) that "Several journals here and abroad have been threatened with loss of pharmaceutical advertising unless they were willing to interdigitate text with advertising pages. Such pressure originating, I would hope," he said, from the "unconscionable competition of advertising agencies rather than the pharmaceutical houses themselves."

Our experience with the staffs of various of our advertisers has been felicitious. We have told them what we would publish and what we would not publish. An ad hoc in-house committee passes on the appropriateness of all ads, and three "outside" psychiatrists are used as consultants when questions arise. This procedure has worked out to our satisfaction. We operate on the principle that our colleagues are mature, intelligent, professional people, and we know that simply because they read an ad does not mean they will start dispensing the substance to all and sundry. We have too much respect for them to think that.

THE CRAFT OF EDITING

Richard M. Hewitt (6), distinguished former editor of the *Mayo Clinic Proceedings*, divided editors into professionals, those who are full-time and of long experience, and amateurs, whom he described as individuals who are part-time, expert in some branch of medicine, and likely to know the authors who are writing in the field. The editor also should know what has been done and what needs to be done so that he can solicit papers in areas that have not received sufficient coverage. Few medical editors are born to the purple; most of us come in the plebian entrance, the back door if you will.

The editor must also possess dogged independence. An editor of a journal owned by a professional society could be in an awkward position. If the editor is complaisant, the journal might become little more than a house organ reflecting the views and wishes of a group or a faction of it. Such a journal might well serve these groups, but it would not be a good scholarly publication and would eventually lose ground and disappear. Fortunately, those of us on the *Journal* staff have never encountered interference from any source during our tenure of office.

Medical journals in general are said to be in poor health at present, and the future of a number of them is in doubt. There is evidence of Cheyne-Stokes breathing in a few. Others, while still alive, are stodgy, dull, and a bit pedantic. Actually, the function of a journal is to give information to its readers, "some of it new, some of it old, some rearranged, some [illegible] some publishable because of their logic, [illegible] and departure from the commonplace" [illegible]

As is the case with many other journ[illegible] number of papers we receive are much too [illegible] lix, and discursive. Some are more peri[illegible] publishable. Some are larded with unnece[illegible] it is not necessary for the readers to know [illegible] pig's temperature at 4 a.m. on a given Thu[illegible] see every detail presented and re-presente[illegible] tables. The question is what were the result[illegible] bearing do they have on the purpose of the [illegible] regularly return papers and ask authors to [illegible] and eliminate some of the myriad of tables [illegible] This is not done in pique—there just is [illegible] *Journal* space to say things two of three [illegible] Theodore Fox (8), former editor of *The J*[illegible] said,

> The editor's real task is to make every w[illegible] to do this he must criticize, revise and abo[illegible] This is not the best way to make friends but [illegible] way for the editor to serve both his authors [illegible] ers.

The fact that psychiatry arrived late a[illegible] specialty (although it treats one of the olde[illegible] known to man) sometimes presents a spec[illegible] for the editor hesitates to reject a paper t[illegible] bit far out lest it really have some therap[illegible] bility. The referees are often ambivalent [illegible] sponsibility rests squarely on him. Une[illegible] head that wears the editorial crown! Dec[illegible] the paper and add to his backlog, or reje[illegible] chance miss something that might bring bra[illegible] the future? Then, too, he must remember [illegible] the author's brain child, his labor of love. [illegible] jor responsibility of the editor is to his [illegible] must be the thumbs up or thumbs down of [illegible] or more gently, the binding or loosing of [illegible]

The editor oftimes must serve not only [illegible] a mediator but also as a translator. When [illegible] referee writes as his opinion that "this p[illegible] unpleasant odor and could do with some[illegible] ener," the editor's task is to avoid decapit[illegible] the [illegible] pectant author by softening the harsh [illegible] writes to the author that, "sadly, this pape[illegible] for us. . . ." Ingelfinger calls this "exce[illegible] around the rosy" (9). "Although your [illegible] pressed me with its many admirable featur[illegible] ments of the readers are such as to make [illegible] for us to publish it." The editor can give [illegible] sons for the rejection but must be careful [illegible] courage a writer who should be encourag[illegible] ue and refine his work or encourage one [illegible] not.

Any decision by an editor and his st[illegible] volves numerous considerations. First, [illegible] are read by many individuals outside of [illegible] fession. Sometimes a paragraph of an arti[illegible] out, amplified, and disseminated far and [illegible]

news media. Some statements that are harmless on the surface can be completely misunderstood and turn up in a Congressional hearing considering changes in medical practice. Others may be used as fuel in the ever-increasing number of malpractice suits. The attentive reader of the daily press will encounter many denigratory comments about physicians that are taken from articles in which the doctors have found fault with themselves and their colleagues. Such articles may even be the basis of legislative actions. Medicine is one of the few professions that pillories itself mercilessly in print and in public, and the complainer may later read his own words quoted back to him in a lawsuit. He may have tossed off some frilly *bon mots* in a moment of enthusiasm and years later find these ill-conceived utterances prominently displayed in public print and enjoying a vast circulation. Medicine today is the stuff of the news media—miracle cures, the carcinogenic potential of many everyday substances, and, especially, the untold wealth of physicians are all grist for the media mill, and the editor must regularly recall these facts to writers.

There are a number of situations that raise the editor's hackles—the most annoying is to find that an article he published had been published elsewhere, either in large part or in toto. Then there are some individuals who have one idea or one particular approach to a subject and they "milk it" for all it's worth—and sometimes more. It might be good for four or five papers on the same study to be distributed to journals at home and abroad. Personally, I do not mind being sent a reprint of an article that I turned down which was published elsewhere. In that case, I am happy for the author.

All editors receive a number of preliminary reports accompanied by an urgent letter suggesting immediate publication to establish priority of an idea. Caution flags should go up and sound advice should be solicited in these cases. One fears publishing misleading information that may have to be corrected later. The situation is especially difficult when an author's presentation at a convention has been given widespread publicity—the editor then gets the paper and a mass of Xeroxed newspaper articles showing how this new discovery will do some miraculous thing. The half-life of some of these well-publicized discoveries is very short, and the editor must be concerned about misleading his readership. When we attempt to cool the author's ardor we sometimes only convince him that we are morons who stand stuffily in the way of great discoveries.

As we began editing the *American Journal of Psychiatry* in 1965, the Association had 13,800 members: today there are 25,000. More of our colleagues are writing than ever before, and for a variety of reasons—building up a bibliography for promotion purposes, acquiring continuing education credit, and, perhaps most often, because they have something important to share with their colleagues. Some authors see the editor and his staff as helpers; others are sure they are obstructionists in the pipeline of true knowledge. The editor, kinder people say, is a checkpoint the writer has to pass—a frontier past which he must make his way before he goes out into the literary world. Some feel simply that the editor's parents were not properly married.

Sir Theodore Fox finds worst of all are those editors to whom rules of grammar are one of the fixed points in an otherwise unstable universe and who are emotionally affronted if an author breaks a rule. The editor, he says, is mostly right but sometimes wrong. "Nevertheless, I stick firmly to my opinion that the quiet subliminal below stairs labour of editorial staffs does a great deal to improve communication among doctors by making the average article clearer and less unreadable" (8, p. 10). I would add to that, "by detecting bloopers that the referee and the editor might have missed to someone's embarrassment."

This Editor agrees that the staff's work is invaluable, and they manage to keep many barbarities of language out of the *Journal*. It is true that some authors will not allow their pristine prose to be tampered with no matter what the *Journal* rules might be, but this is infrequent. We deal with such instances by carefully going over the segment in question again; if we are right we send the author a Xeroxed copy of our authority for our action; if we are wrong we admit it and make amends.

WRITING FOR MEDICAL JOURNALS

No paper by an editor would seem to him to be complete without some comment about writing, even though his own productions might not be on the level of the King James version. Writing is said to be at least a craft and at best an art. All can agree that writing should be beautiful if possible. It is said that it needs taking only a little more trouble in order to make it pleasing to writer and reader. Pickering observed that "since we have each but a brief spell on earth, why not make that experience enjoyable?" Unfortunately, however, we all sometimes feel like Gustave Flaubert, whose writing irritated him. "I am like a violinist whose ear is true," he said, "but whose fingers refuse to reproduce the sounds he hears within."

Critics with literary sensibilities often comment wittily about the outrageous style of some such scientific writing. Scientists, they say, use jargon because they are obsessed with the desire to show that their work really does belong within a reputable context. Hayakawa commented that some doctors seem to hold to a tradition that goes back to the Chou Dynasty in China and to ancient Greece—the assumption that you can never be respected as a man of learning if everyone understands what you say. In past ages, intellectuals talked to each other in Latin, Sanskrit, or Classical Chinese, always making sure these languages were no longer spoken. The dead languages performed the extremely useful function of keeping the peasants in awe-

struck reverence before mysteries they could not hope to understand.

"We no longer encounter Sanskrit, but we do occasionally encounter jabberwocky. If one wants to try to make his paper read well, let alone glow, one does not have to perspire over it; one simply says what he means in simple declarative sentences. It is, however, desirable to get away from the "plop plop" style we so frequently encounter in medical writing. Some writers take a simple statement, choke it to death with adjectives, put as much as they can in the passive voice, and then embalm it further in polysyllables, making it more un-understandable.

The editor of a medical journal has some idea of what his readers want, and he can even try to find out for certain in readership surveys and by careful attention to his correspondence from readers, but even these facts must not overwhelm him. He must proceed carefully, for the specialties do not stand still, and it is the editor's job to recognize the advances. He must therefore present the material in a manner that will appeal to as many of his readers as possible. It was Alan Gregg who called to our attention the fact that easy writing was generally damn hard reading. The editor, therefore, cannot be overwhelmed by the name of the author: his reputation may be great, but we are publishing his work, not his biography.

The title and first paragraph of an article are important, as is the blessed précis. Doctors will not be enticed by an article whose title and early habiliments are dull, for there is too much reading material available and too little time to read it. Also, titles must lend themselves to proper categorization if they are to appear in the various medical index journals. The golden rule is to write, rewrite, rewrite again, and polish. Plato is said to have written the first paragraph of *The Republic* 12 times, and few of us are of the calibre of Plato.

We of the *AJP* have only occasionally encountered difficulties with titles. Other journals are not so fortunate, and we may be excused for appropriating the report of one instance. Robert A. Day (10), the outstanding Managing Editor of the publications of the American Society for Microbiology, wrote on the necessity for care in the syntax of titles. Most errors in titles, he pointed out, are due to faulty word order. One article he quoted as an example was entitled "Preliminary Canine and Clinical Evaluation of a New Anti-Tumor Agent, Streptovitacin." Day observed that "When that dog gets through evaluating Streptovitacin I've got some work I'd like him to look over." Incidentally, he said, the abstract of that article revealed that only male puppies were used. He thought perhaps a better title might have been "Evaluation of Streptovitacin in Sons of Bitches."

Just one or two further comments about doctors writing before I desist. William Bean warns us in talking about patients and in writing about them we should "avoid the good old zoological labels, 'male' and 'female,' . . . It is just as easy to say man or woman, girl or boy. . . . We don't refer to our children as [illegible] year-old white males, we call them little boys [illegible] devils). Few of us would introduce our mother [illegible] Maggie from Dubuque as a charming fifty [illegible] seventy-year-old white female" (11, p. [illegible]). Dr. Bean goes a bit further than I would when he states, "A patient may properly be on a bed or on a bed [illegible] but not on digitalis or on a high-fat diet [illegible] into the soup."

There is a barbarity that distresses me greatly [illegible] curs when physicians describe "cases" (to which [illegible] so object), saying "The patient *presents*. [illegible] sents"—that's what female baboons do in those [illegible] pictures we see of simian colonies in Africa.

I will spare you further examples of execrable [illegible] language, but I would like to note that there [illegible] papers which have very little to say and yet say it [illegible] Sometimes writers object to our returning [illegible] for "rewriting, tightening, and pruning." However, once an article is printed, it remains forever [illegible] on paper, and in the future it might not be [illegible] encounter early reminders of one's handiwork [illegible] probably should not have been written in the first place.

Brevity is the elixir that makes editors' lives pleasant. Clearly, briskly writing is a joy to read. [illegible] no courses and no "how-to-do-it" books [illegible] writer. It has to be done by ordinary folks [illegible] ing and rewriting and plugging away, practicing [illegible] criticism, striking out unnecessary words [illegible] writing it over again. Remember, too, that [illegible] nals are painfully short of space, but one must be careful of "overabbreviating." "S.O.B." [illegible] for "shortness of breath," but it also has [illegible] notations.

If you will pardon these professional observations, I will tell you modestly that I learned most [illegible] learned editing. Our own *Journal* is less particular about grammar than it is in asking that the author be clear in the message he intends to get across. The copy editors can put papers in the Queen's English, but they cannot tell what a man is thinking.

READING—HOW DOES ONE GET THE TIME?

In Boswell's *Johnson* it is written that the greatest part of a writer's life is spent in reading. [illegible] turned over half a library to write one book. The best way for a modern medical writer undoubtedly [illegible] familiarize himself with the thoughts and words of the finest members of the human race down through the ages. This can be done by getting into the habit of reading briefly every day in some field, even in the face of the overwhelming burden of study, and by a profound determination to attain excellence.

We as physicians are all awash in a sea of [illegible] literature. How can we handle this and make our reading effective? In our time there will always be too much to read; we must read selectively, wisely, and

despair not. Richard Orr (12) states that while there is no magic way, one secret is to follow several rules:

1. Speed—the ability to read very quickly is common among practitioners who are on top of the literature rather than under it.
2. Selection—sorting out printed materials that arrive into three piles: 1) requiring only a quick glance, 2) deserving of at least 5 or 10 minutes of rapid scanning, and 3) meant for more extensive study and reading only the parts that promise maximal return (read the summary first).
3. Optimum use of time—everyone of us has a few moments of free time during the day.

Felix Marti-Ibanez was a master at using these moments—he called himself "a ragpicker of time," and he read and wrote a prodigious amount. However, there is no habit which one can more easily take up or more easily put aside as other duties press upon one.

THE FUTURE

What of the future of journals like our own, which are inundated with manuscripts? Some feel that they have little future, for doctors will soon prefer newer techniques. Sir Theodore Fox believes that most of the scientific periodicals will disappear and be replaced by computerized material that could be made available through great centers which the seeker could tap at will. Morris Fishbein, an excellent editor, thought that we are in an evolutionary period and still have time before the computers take over. Actually Sir Theodore's idea is that there would be "recorder journals," "newspaper journals," and an intermediate group trying to be both.

It is my belief that journals as we know them will continue for many generations. They remain lying quietly until they are needed, but in them are recorded the thoughts, dreams, and hopes of those who for centuries have gone before us. Our own *Journal* gives a good example. In it one can trace the history of modern psychiatry from its beginning in this country to the present. We see various ideas emerge and methods tried, disappearing after a time only to rise again later or, perhaps one step higher in the scale. Then, too, the modern researcher wants to have a look at all of the reports of colleagues in his particular field, and good scientific libraries make it easy for the researcher to peruse what he wants to, when he wants to.

One serious concern is the great mass of material being presented to the *Journal* for possible publication. A long lag time before publication is worrisome, and when it extends to a year it becomes distressing to everyone, for many articles are time-limited. At present a committee of our Editorial Board is examining our particular problem and all hope fervently that some answer will be found.

As I leave the editorial chair I do so knowing that the *Journal* is in excellent hands. An editorial office furnishes a marvelous perch from which to observe the overall scene in a medical specialty and I am grateful that I was part of an excellent office in a time of transition. A great deal happened in my 13 years as Editor. Old age and death were "discovered," and these subjects interested me for obvious reasons. A plethora of papers on these subjects and on drugs, licit and illicit, appeared—some good, some not so good. We watched the incredible advances in psychophysiology and psychopharmacology with great pleasure, and we watched disconsolately the failure of some of the community mental health centers to live up to expectations.

From the vantage point it was my privilege to occupy, it has seemed for the last decade that psychiatry was slowly making its way back into medicine, the discipline that nurtured it and from whence it sprang. As it has developed potent therapeutic tools, psychiatry's drift toward medicine has become more apparent. Actually, there are large numbers of psychiatrists who never felt they had left medicine's protective boundaries at all. Nevertheless, the return of the prodigal psychiatry as a specialty to medicine should be a felicitous one.

Personally I am indebted to many people. I have already written and spoken of my affectionate regard for my colleagues on the *Journal* staff and for the Editorial Board. The Board was carefully selected and consists of colleagues who are expert in some aspect of our field. I am deeply indebted to each one of them—they have been helpful always and patient with my calls for help. I shall never forget the kindness, helpfulness, and capabilities of all of them, and I shall not worry about what the future holds for me as long as I can take my memories of all of these wonderful people with me.

As to my future plans, a scheme outlined by Edward A. Reinhard (13) did appeal to me—but only briefly. He spoke of retiring in a few years and getting a big rocking chair. He said, "I shall rock very slowly, read what I want to read and watch the younger lemmings try to avoid getting pushed off the cliff and drowning in an ocean of abstracted, translated, computerized dehumanized data." I thought of that possibility for a while, but then I became afraid that perhaps legislatures, judges, lawyers, and civil libertarians might push our own young colleagues off the cliff; they are working at it at the moment. It was then that I decided not to rock; instead I shall stay on the beach and try to be lifeguard for any of ours that do come over the cliff. I was a lifeguard before I went into medicine and I may as well go out that way. I'll be slower to the rescue, mind you, but I'll be just as intent and just as interested while I retain any faculties at all.

Is Modern-Day Schizophrenic Outcome Still Negative?

BY MARTIN HARROW, PH.D., ROY R. GRINKER, SR., M.D., MARSHALL L. SILVERSTEIN, PH.D., AND PHILIP HOLZMAN, PH.D.

To evaluate formulations about more positive outcome in modern-day schizophrenic patients, the authors assessed 132 young patients 2.7 years after hospital discharge. Despite modern treatment techniques, only 14%–17% of the 79 schizophrenic patients in the study group were functioning effectively without relapses; 50% had adjusted very poorly. The schizophrenic patients were functioning significantly more poorly than the nonschizophrenic patients in all areas ($p<.01$), showing poor adjustment, high symptom levels, and high rehospitalization rates. The two major acute subgroups (schizo-affective and acute schizophrenic patients) were functioning better than those with paranoid and chronic schizophrenia. Overall, the authors conclude, diagnosis carries prognostic implications. Schizophrenic outcome is more favorable today than it was in Bleuler and Kraepelin's era, but it is still relatively negative.

REALISTIC GUIDELINES on schizophrenic outcome are relevant to theories about the nature of psychosis and are of value to the practicing psychiatrist. Detailed information in this area is all the more important in light of reports of changes in prognosis for schizophrenic patients over the last decade. Traditional beliefs about negative outcome in schizophrenia have been challenged by several recent trends.

One of these trends involves the widespread use in the last 20 years of more effective pharmacological treatments (1–4). The original hope was that the use of phenothiazines would drastically alter the negative outcome traditionally associated with schizophrenia. The traditional view of an extremely negative prognosis was believed to be a characteristic of schizophrenia as recently as 1941, when Kant (5) observed that the recovery rate for schizophrenia was only 1%–7%.

Clinical observations about improvement in outcome for schizophrenia since the advent of more modern treatment techniques have been buttressed by the findings of Strauss, Carpenter, and Hawk (6, 7) in an important program of follow-up research. Their results showed a more positive outcome for schizophrenia than would have been anticipated by most theorists. Similarly, in a 1974 follow-up study of schizophrenic and nonschizophrenic patients (8), members of our research team also reported smaller differences than anticipated between schizophrenic and nonschizophrenic patients, although there were significant differences in favor of nonschizophrenic patients. Although several recent studies have cast some question on the traditional belief in a negative schizophrenic outcome, two recent studies of ours (9, 10) found a surprisingly high degree of symptomatology in schizophrenic patients after the acute phase of their illness.

The reports about a more positive outcome in schizophrenia pose questions concerning our standard concepts of this disorder. A central belief associated with the diagnosis of schizophrenia involves ideas about a negative outcome. This belief is important historically in concepts of dementia praecox and is still prominent in current theory about schizophrenia.

In the research reported on here, part of a larger project studying the long-term course of schizophrenia (10–14), we attempted to resolve some of these issues about outcome for modern-day schizophrenic patients. In particular, we focused on the following four questions related to schizophrenic functioning during the postacute period: 1) Do schizophrenic patients function more poorly than nonschizophrenic patients during the postacute phase? 2) What percentage of schizophrenic patients have a very poor outcome, and what percentage of schizophrenic patients can be expected to have a very favorable outcome? 3) If schizophrenic outcome is negative, which specific areas of functioning are affected, or is the poorer functioning spread across all areas? 4) Do certain schizophrenic subgroups function more poorly than other subgroups? Put another way, does schizophrenic subdiagnosis make a difference?

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

METHOD

Patient Sample

To study young schizophrenic patients during relatively early phases of their disorder, we assessed, at the time of hospitalization, 132 inpatients at Michael Reese Hospital (median age=23.5 years, range=17–34 years) and then reassessed them an average of 2.7 years after hospital discharge. The patients were almost entirely from social classes I, II, and III according to the 5-point Hollingshead and Redlich system. These patients were part of the ongoing multidisciplinary schizophrenia project that has been conducted at Michael Reese Medical Center and the University of Chicago since 1970 (10–13).

The sample included 79 schizophrenic patients and 53 nonschizophrenic patients diagnosed by the consensus of two senior clinicians using *DSM-II* (15) criteria. The schizophrenic population included subsamples of 7 patients with schizo-affective schizophrenia, 11 with acute schizophrenia, 22 with paranoid schizophrenia, and 28 young patients with chronic schizophrenia. The nonschizophrenic sample was composed of 28 patients with depressive disorders, 16 with severe personality disorders, and 8 with other diagnoses.[1] There were no significant differences between the schizophrenic and nonschizophrenic patient samples in age, education, and intellectual level.

At the time of follow-up, 46% of the schizophrenic patients were on phenothiazines. During the postacute period schizophrenic patients on phenothiazines were functioning significantly more poorly than schizophrenic patients not on phenothiazines on the major indexes of outcome ($p<.01$, t test). In many cases, however, their poorer clinical conditions may be the reason they were being treated with phenothiazines. The schizophrenic patients receiving psychotherapy at follow-up did not differ in overall outcome from those not receiving psychotherapy. Caution in interpreting the results comparing different medication and psychotherapy groups is warranted because patients were assigned to the medication groups or to psychotherapy on the basis of clinical condition and/or other factors rather than on a random basis.

Posthospital Adjustment

The follow-up assessment of the 132 schizophrenic and nonschizophrenic patients included a structured interview (8, 17), a series of performance tests and projective tests, and several questionnaires, including the Katz Adjustment Scales (18). The follow-[illegible]ule involved detailed evaluation of the follo[illegible]g 1) social, work, and family functioning, 2) the pa[illegible]s's subjective evaluations of their own mental he[illegible]h 3) the patients' intellectual level, 4) their use of [illegible]cation and posthospital treatment, 5) their poten[illegible]e depressive, and psychotic symptomatology [illegible]schotic symptomatology was assessed by means of [illegible]3) form of the Present State Examination (1[illegible]6) hospitalization. The present research focu[illegible]n the patients' level of functioning as assesse[illegible]e evaluating five specific areas of adjustmen[illegible]f adjustment, work or instrumental functionin[illegible]n outcome, rehospitalization, and suicide).

Two scales of overall adjustment were [illegible]. These included a scale developed by Le[illegible]n associates (16) used in the past in seve[illegible]n tions by others (16, 19) and by members [illegible] research group (17, 20). This overall scale [illegible]es the areas of work and social functioning, life [illegible]ns self-support, symptomatology, potential [illegible]e lapses, and rehospitalization. The second [illegible]s was one used by Strauss and Carpenter (6[illegible]in vestigations of posthospital functioning. T[illegible]d vidual scales covering specific areas [illegible]d by Strauss and Carpenter were used to allo[illegible]t rect comparison of the current sample w[illegible]ied by others.

RESULTS

Results for Schizophrenic and Nonschizophrenic Patients on Overall Functioning

Table 1 presents the data for the schiz[illegible]ic and nonschizophrenic patients on Levenstei[illegible]n ates' index of overall functioning (16) for [illegible] of the follow-up period and for the comple[illegible] period. Several major features concern[illegible] level of functioning of the samples can be [illegible] 1.

The schizophrenic patients as a grou[illegible] significantly more poorly than the nons[illegible] patients during the entire follow-up perio[illegible] despite extensive use of phenothiazines [illegible] therapy. A core group of schizophrenic pa[illegible] 50%) had adjusted *very* poorly; these p[illegible] negative outcome in the two major [illegible] symptomatology and a low level of func[illegible] sidered as a group, the schizophrenic pat[illegible] a high rate of rehospitalization; 62% o[illegible] phrenic patients had been rehospitalize[illegible] times since the index hospitalization.

These outcome results are superior to [illegible] years ago during Bleuler and Kraepelin's [illegible] still represent an extremely low level of [illegible] is possible that our modern treatment [illegible] not as effective with certain types of pa[illegible] the core group of patients with severe c[illegible] cox who had an extremely negative outc[illegible]

[1]The results on outcome for the 132 patients include data for 7 patients who committed suicide during the follow-up period. The results on these 7 patients are included in the data on overall outcome in the major measure used (the Levenstein-Klein-Pollack Outcome Scale [16]) to provide a representative picture of overall outcome. However, since they could not be interviewed, data for these 7 patients are not included in the results on such individual areas of functioning as social and symptomatic functioning. They are also not included in the results using the Strauss-Carpenter total outcome score, in accordance with Strauss and Carpenter's system of calculating these results (6), and to allow for comparison of results across samples using the same techniques.

of Kraepelin. In contrast to these patients, it may be the large group of middle-outcome schizophrenic patients who profit more from modern treatment techniques, who now function somewhat more effectively, and who are no longer placed on back wards or "continuous treatment units." These middle-outcome schizophrenic patients now seem to experience mild to severe difficulties in functioning and sporadic rehospitalizations rather than severe deterioration. Thus, middle outcome schizophrenic patients are still functioning far below the level of the typical "normal" person in our society.

When one looks for the schizophrenic patients who were functioning adequately in all three areas during the postacute phase (functioning at a high level socially and occupationally, with no relapses or rehospitalizations and no symptomatic difficulties), one finds that in our sample only 14%–17% fit into this category. This low rate is, at best, only slightly superior to the rate 70 years ago.

The large significant differences we found between diagnostic groups are not completely concordant with Strauss, Carpenter, and Hawk's data (6, 7), which suggested smaller (but still significant) differences between schizophrenic and nonschizophrenic patients. When the same indexes of functioning used by Strauss and Carpenter (6) were used, our 73 schizophrenic patients who were interviewed were found to be functioning significantly more poorly than our nonschizophrenic patients ($t=5.88$, $p<.001$, two-tailed). Our schizophrenic patients were functioning more poorly than the Strauss-Carpenter sample (the mean score on the Strauss-Carpenter index for our schizophrenic patients was 9.70). In addition, our nonschizophrenic patients were functioning at a slightly higher level than the Strauss-Carpenter nonschizophrenic sample (the mean on the Strauss-Carpenter index for our nonschizophrenic patients was 13.38). Although our schizophrenic patients had poorer scores than the Strauss-Carpenter sample in most individual areas of functioning, our patients had a slightly lower rate of rehospitalization.

The nonschizophrenic patients as a group showed a different pattern of postacute functioning. In contrast to the schizophrenic patients, almost none of the nonschizophrenic patients had a very poor outcome. Over half of them showed a favorable outcome, and most of the others showed an equivocal outcome. The nonschizophrenic patients with an equivocal outcome experienced some difficulty in terms of continuous symptomatology, relapses and/or rehospitalization, or life disruptions and difficulty in functioning. Thus, although the nonschizophrenic patients' outcomes were more favorable, a large number of nonschizophrenic patients experienced difficulty in one or two areas (as opposed to experiencing considerable difficulty in all three major areas, as was found for many of the schizophrenic patients).

Differences Between Schizophrenic and Nonschizophrenic Patients in Various Areas of Functioning

Tables 2–4 show the differences between the schizophrenic and nonschizophrenic groups in various areas of functioning during the posthospital period. The poorer posthospital adjustment of the schizophrenic patients in comparison with the nonschizophrenic patients is not limited to one area of functioning. The differences cut across all major areas at statistically significant levels. This includes significant differences in the social area, in instrumental performance (or functional work role), in extent of psychotic symptomatology, and in rate of rehospitalization.

There were significant differences between the schizophrenic and nonschizophrenic patients in psychotic features and in certain types of thought pathology (see table 3). However, the schizophrenic dysfunctioning during the follow-up period did not occur only in areas related to psychotic symptoms. Many of the greatest differences between the diagnostic groups oc-

curred in nonsymptom areas, indicating that the long-term course of schizophrenic psychopathology after the acute phase is not limited to symptom difficulties.

A drastic decline in social skills and social functioning has been proposed by some theorists as the major factor associated with schizophrenic deterioration. The data on the present sample at the 2.7-year follow-up period showed significant differences in social functioning between the schizophrenic and nonschizophrenic patients (see table 2). These included at least some difficulty in terms of sociability (poorer quality of relationships and less frequent association with friends) and some difficulties with spare-time activities. The social area, however, was not the area of malfunctioning showing the greatest differences between the two groups.

The area showing one of the largest significant differences between the schizophrenic and nonschizophrenic patients during the first 2.7 years after the index hospitalization was that of work or instrumental functioning (see table 2). A large percentage of the schizophrenic patients showed at least some difficulty in instrumental performance. This was very striking among the men: three-fourths of the schizophrenic men showed at least some difficulty, or less than adequate functioning, in performance in their societally expected work role.

*df=1.
**Schizophrenic versus nonschizophrenic patients.

The schizophrenic patients also tended to evaluate their own mental health in a less positive light than did the nonschizophrenic patients (p<.01, chi-square), possibly in part because of some realistic evaluation of their difficulties in functioning. Although all but a few patients in both diagnostic groups evaluated their psychological state in less than optimal terms, the majority of the patients did not tend to have a severely negative outlook.

Another area of importance concerns suicide. Six of the 79 schizophrenic patients (7.5%) committed suicide during the follow-up period. This is a high rate. It must be kept in mind that the current sample of schizophrenic patients was a relatively young one, and the possibility exists that some of them had experienced considerable difficulty in adjusting to the disappointments and frustrations associated with their problems in functioning and their intermittent or chronic failures. This may have been a factor in some of the suicides. Other experienced clinicians have noted that one can expect a suicide rate of 5% or higher in young schizophrenic patients, and this is in accord with our previous experience in other settings. It is quite possible that an older, chronic, multi-year schizophrenic sample with lower expectations would have a lower suicide rate.

The data on rehospitalization (see table 4) showed significant differences between the schizophrenic and nonschizophrenic patients and also indicated considerable absolute malfunctioning for the schizophrenic patients. Thus, despite the use of modern treatment techniques and aftercare, 62% of the schizophrenic patients had been rehospitalized at least once after the index hospitalization, and at the time of the follow-up assessment 19% were in the hospital. This high rate of rehospitalization is roughly in accord with data on schizophrenic samples recently presented by other investigators. In contrast to the high rate of rehospitalization among the schizophrenic patients, 35% of the

*According to the Levenstein-Klein-Pollack Outcome Scale scores (16); 1–2=good, 3–6=equivocal, 7–9=poor.
**Good versus equivocal versus poor outcome/schizo-affective and acute schiophrenic groups versus chronic and paranoid schizophrenic patients.

nonschizophrenic patients had been rehospitalized since the index hospitalization.

When the data on the various areas of functioning are viewed from a broader perspective, the importance of such areas of adjustment as work and social performance become apparent. Although work and social dysfunctioning are often seen as secondary symptoms, during the course of the disorder these secondary features become equally or more important than the primary (psychotic) symptomatic features in terms of overall adjustment. If the poorer functioning in work and social areas are really secondary features, do we yet know what the more important or primary aspects are (14, 21)?

Since the schizophrenic patients' dysfunctioning affects almost every area of their postacute performance, it is not surprising that the index showing the largest significant differences between the schizophrenic and nonschizophrenic patients during the posthospital period should be the overall index. The broadest overall index (the Levenstein-Klein-Pollack Outcome Scale [16]), which reflects a number of difficulties for the schizophrenic patients cutting across a variety of different areas, showed the largest significant difference. This result of maximum difference between schizophrenic and nonschizophrenic patients during the postacute phase on the broadest overall index is in accord with data we reported on a different sample living in a different geographic area (8). In addition, the posthospital adjustment of the present schizophrenic sample is similar in some respects to that found in a sample assessed by Levenstein and associates (16) using the same overall index of functioning.

Differences Between Schizophrenic Subdiagnostic Groups

Table 5 presents the overall results for the major schizophrenic subgroups. There was a trend for the two major acute schizophrenic subgroups (the schizo-affective and the acute schizophrenic groups) to show better functioning on the scales of overall functioning, compared with those with chronic and paranoid schizophrenia ($p<.05$). The trend toward poorer functioning among the chronic and paranoid schizophrenic patients was most prominent in the social area ($p<.05$). In the area of work or instrumental performance, the chronic and paranoid schizophrenic patients also showed slightly poorer functioning than the two more acute schizophrenic subgroups, but the difference in this area was not even close to significant. The chronic and paranoid schizophrenic patients had more psychotic symptoms during the postacute phase, but the differences were not significant.

As can be seen by these results on diagnostic subgroups, the trend toward poorer posthospital functioning among chronic and paranoid schizophrenic patients occurred in all major areas of functioning. In a few areas the poorer functioning of the chronic and paranoid schizophrenic patients was at significant levels, but in most areas the differences were much smaller and not significant. These consistent differences across all major areas suggest that there may be some basic differences among subtypes; however, the interpretation of these results suggests several possibilities.

It should be remembered that our group of chronic schizophrenic patients with poor outcome are young patients who have not had years of hospitalization and who are being studied at a relatively early stage in relation to a possible long-term course of future schizophrenic or psychotic breaks. Some studies that have found poorer outcome among chronic schizophrenic patients have used samples of older patients who already had a history of many years of hospitalization. The latter type of research presents a problem because it involves "findings" of subsequent poor outcome for certain subtypes of schizophrenic patients who have

already had many years of poor outcome and hospitalizations before the study—not a very remarkable finding.

Of considerable interest, the differences between the chronic and acute schizophrenic patients in symptomatology and functioning were greater (more negative for the chronic schizophrenic patients) at the posthospital or follow-up period than at the acute phase and during the hospital period, when the original diagnosis was made.

If the severity of schizophrenia is assessed in terms of a negative outcome, our results on differences in outcome between schizophrenic subgroups that had only small to moderate symptom differences at hospital admission support our previous data and formulations in this area. Our previous data (8, 22) suggested that in schizophrenia, unlike some other disorders, the severity of the disorder should not be assessed in terms of the severity of the symptomatic picture during the early active phases of the disorder (e.g., at the time of hospitalization). Rather, factors such as early onset of the schizophrenic disorder and poor premorbid functioning (at times in the social-sexual area) may be better, although still imperfect, indexes of severity of the underlying schizophrenic disorder.

DISCUSSION

Our outcome results have implications for a number of related issues. The current somewhat pessimistic results on schizophrenic outcome should be considered in relation to the increased optimism that has emerged with the advent of more modern treatment techniques.

We sometimes hear that diagnosis is not important today because overall outcome depends on the particular individual and the particular treatment. The form of treatment involved undoubtedly makes some difference, but this does not tell the whole story. The large significant differences we found, as well as the data of Strauss and Carpenter (6), strongly indicate that diagnosis is an important factor; modern-day schizophrenic patients as a group still show a relatively negative outcome.

The poor outcome associated with schizophrenia applies to a number of different aspects of functioning. Both the symptomatic picture and the functioning level of the schizophrenic patient in other areas are negative. The present data suggest that the posthospital picture of schizophrenia is not just a case of debilitating symptoms. In the current sample the postacute work and social functioning of the schizophrenic patients showed large significant differences in comparison with nonschizophrenic patients.

It is difficult to compare the present negative results on modern-day schizophrenic outcome 2.7 years after hospitalization with those found for schizophrenic patients earlier in this century. Precise comparative figures on earlier samples assessed many years ago are not available to make exact comparison possible. The current-day schizophrenic patient functions better after hospitalization than he or she used to. One type of evidence supporting this contention can be found in the indications that many years ago a much larger percentage of first-break schizophrenic patients never left the hospital after their initial or second hospitalization. Although the present data and other results point to the fact that many modern-day schizophrenic patients do not function as poorly as was the case during the era of Bleuler and Kraepelin, the results clearly show that as a group they do not have a benevolent outcome. Only a small percentage of our schizophrenic patients (14%–17%) functioned at a high level without relapses after hospitalization, and a large percentage (about 50%) tended to have a very negative outcome.

The present results do *not* support the observation made by some investigators that one-third of schizophrenic patients function well after treatment, one-third perform in an equivocal manner, and one-third function poorly. These estimates do not apply to the schizophrenic patients we studied, except in the area of work functioning. Further, the assumption that schizophrenic outcome is similar to that of other psychoses was not supported by our data. The majority of the nonschizophrenic patients showed at least some residual or recurring difficulty in functioning but their levels of both symptomatology and difficulty in functioning were not as severe as those of the schizophrenic patients. The differences between these patients and the schizophrenic patients was very large.

The current results suggest a mixed picture. With our modern treatment modalities most schizophrenic patients fare better than they would have in the days of Kraepelin and Bleuler (they no longer experience continuous or even lifelong hospitalization). However, the outcome for the modern-day schizophrenic patient is still a relatively negative one.

Diagnosis of Nonpatients in the General Community

BY FREDERICK S. MENDELSOHN, M.D., GLADYS EGRI, M.D.
AND BRUCE P. DOHRENWEND, PH.D.

Using a sample of 116 subjects drawn from a large metropolitan area, the authors compared ratings of psychopathology from both structured and clinical interviews. Although the two types of interviews yielded similar findings when there was definite psychopathology or definite signs of health, for some subjects in the middle range between health and sickness, the two interviews did not yield similar findings. The authors suggest the need for a new typology to categorize nonpatients in the community who are in the middle range between frank psychiatric disorder and optimal mental health.

ACCURATE knowledge of the prevalence and distribution of psychiatric disorder in the general population is necessary in order to test a number of etiological hypotheses, e.g., social class as a causative factor in the development of mental illness. To date, at least 58 studies throughout the world have attempted to measure psychiatric disorder in the general population without regard to treatment status (1). The wide variation in reported rates in these studies, of under 1% to over 50%, is due to the contrasting concepts and methods for identifying cases used by different investigators. The focus in this paper will be methodological. We will contrast two different types of research interviews employed and relate them to each other. Some studies employ the usual open-ended clinical interview; others use a structured questionnaire. The main disadvantage of the clinical interview method is that it cannot be replicated by other researchers. The advantage of the structured interview is that the procedures are described in specific detail and are thus capable of accurate replication. Replication of studies is essential if the field of psychiatric epidemiology is to advance beyond its present state, in which varying study results are difficult to evaluate and use for testing hypotheses.

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

The authors are with Columbia University College of Physicians and Surgeons, where Drs. Mendelsohn and Egri are Assistant Clinical Professors of Psychiatry and Dr. Dohrenwend is Professor of Social Science, Department of Psychiatry. METHOD

A total of 116 subjects from the community were interviewed three times over a one-year period using the Psychiatric Epidemiology Research Interview (5). This instrument is a structured fixed-response questionnaire derived from previous work and covers a large number of areas of psychological functioning. In addition to including the more usual questions related to psychotic, psychoneurotic, and behavioral disorders and psychosomatic illnesses, it also tries to uncover indications of positive mental health as well as stressful life events.

The sample was randomly drawn in roughly equal proportions from five New York City ethnic groups (white Protestants of European ancestry, Jews, Irish, blacks, and Puerto Ricans) on a strict probability basis. Within each ethnic group an attempt was made to balance educational levels in order to unconfound social class and ethnic status.

Trained nonpsychiatrist interviewers from the National Opinion Research Center interviewed 74 of the subjects. These 74 were matched with 42 subjects interviewed by 8 different psychiatrists, most of whom had had previous experience interviewing community respondents using other structured research instruments. These psychiatrists, unlike the lay interviewers, rated each subject according to the Midtown Manhattan (6) and Stirling County (7) rating systems and made a psychiatric diagnosis if they thought one was indicated.[1] The psychiatrists were trained to reliably use the Stirling and Midtown ratings. No reliability training was done for diagnosis, and the psychiatrists, who generally had diverse training and experience in psychiatry, were asked to diagnose according to *DSM-II* (8).

Two psychiatrists independently reviewed the 42 written protocols of the subjects interviewed in the field by other psychiatrists. The reviewing psychiatrists selected subjects for a clinical follow-up interview based on the following criteria: there were indications of impaired functioning and/or psychiatric symptoms, psychopathology was not gross or severe, impairment in functioning was not marked, and the clinical picture did not conform to a psychiatric diagnosis according to *DSM-II*. These criteria were established in order to select those subjects who would be most likely to present problems in evaluation and would, therefore, presumably be the ones most likely to have discrepant results on the structured and clinical interviews. Leighton and associates (3) chose their subsample mainly from the categories in which there was little question about whether or not a subject was a psychiatric "case," and they were, therefore, more likely to find agreement between the two interview methods. The rationale for our adopting the strategy of selecting the subjects who were most likely to present problems in evaluation was that if we found the two interview methods to give similar results, it would be strong support for the convergent validity of structured interviews.

[1]The Stirling County and Midtown Manhattan rating systems are well known in the field of psychiatric epidemiology. The Stirling rating, developed by A.H. Leighton and associates, has been used for studies in the Maritime Provinces of Canada and in Africa as well as other places. The Stirling rating is made on the basis of whether a respondent is a psychiatric case. No attempt is made to specify which particular diagnostic category fits the respondent, but only whether one or more diagnoses apply. The rating does not refer to the severity of the diagnosis. The Midtown Manhattan rating system, on the other hand, is based on a gradation of severity of symptoms and impairment.

RESULTS

Eleven subjects were selected for follow-up. Those selected for clinical evaluation had been rated in the structured interview as having less severe symptoms and less impairment in functioning, and they were less likely to be psychiatric cases than those not selected (see table 1). There were no differences in the range of diagnoses between the two groups (see table 2). Three subjects refused or could not be located for a clinical interview. Two of the 11 were clinically interviewed immediately after the third structured interview because the interviewer had many questions about the responses given at that time. One of the 11 would not consent to a fourth interview, but 2 different psychiatrists spoke to her at length over the phone. The remaining 5 were interviewed for the fourth time in their homes by a psychiatrist.

Three psychiatrists reviewed the results from the 8 respondents for whom there were sufficient data for a clinical evaluation. On the basis of a consensus rating the 3 made a final evaluation. In making their final evaluation they had access to the results of the clinical and structured interviews plus all other information collected on the respondents. Thus the final evaluation by which the structured interview was to be compared was based on all of the information available on each of the respondents.

As a result of the clinical evaluation, 6 of the 8 subjects received a change in their rating as to whether or not they were a psychiatric case according to the Stirling County rating system. Three became cases, and 3 who were originally judged to be cases were in the final evaluation judged not to be psychiatric cases. The 2 respondents who required no changes in their evaluation were generally functioning at a high level and reported almost no symptoms. However, they were selected for follow-up because there were indications of psychopathology that may have been missed in the structured interview, admission of some suicidal thoughts by 1 subject, and the other subject's fathering of 2 handicapped children, which frequently results in psychiatric symptoms. Clinical interviews did not reveal anything remarkable in these 2 respondents.

Two respondents had answered positively to some items ordinarily indicating psychosis, but after a clinical interview it was determined that they had misun-

derstood the questions and that no indications of psychosis were present. (For example, to "mind dominated by forces beyond your control?" one respondent said "yes," but in the clinic she explained that she meant "controlled scious forces.") One respondent answere to a few items probing for anxiety, but the did not evaluate her as a psychiatric case viewed her in the usual clinical manner. A cal interview he felt, and the reviewing concurred, that she had evidence of ma and a psychiatric diagnosis was indicated.

In the following 2 cases the respond very little psychopathology in the stru view, but after the clinical interview psychiatrists concurred that a psychiatr present.

CASE REPORTS

Case 1. Mr. A, a 59-year-old man from an nic group, had responded negatively to all item psychopathology with the exception of a few the frequency was "almost never." He was clinical interview because he said that he had the last 12 months.

Mr. A was extremely helpful and cooperat for the interview. In regard to sexual relations, that it was more likely 2 years rather than later in the interview he said that it had been since he had had sexual relations. He told th viewer with obvious discomfort. His wife was and cooperative. The two of them appeared to to get along well with each other. They had t were successful and of whom they were proud, as they showed the interviewer pictu their grandchildren.

The subject had lived in the same neighb since birth. It had originally been middle class slum. His parents were deceased, and all of h sisters and other relatives had long since m more affluent surroundings. His apartment w but pleasant, in marked contrast to the outs hood, which had all the familiar signs of ur poverty.

Mr. A had graduated from high school and showed above average intelligence, but he h able to hold a job much above that of a clerk tried more demanding work, he felt uncomfo He was now earning $125 a week and said th happy with his income and found it easy to liv socialized with other people and rarely saw did not know his brother's occupation bec want to be "nosy" and ask. His parents h and he had been close to his mother, who d years earlier. Paranoid tendencies emerge scribed why he never socialized with anyone people never returned favors, they took adv and they had made his wife sick.

Mr. A smiled constantly. He often went int tail and was irrelevant at times. There w appropriate affect, thought disorder, and pa He had a lifelong pattern of retreating from a resulted in anxiety for him. He had restricted pationally, socially, and sexually. He was di reviewing psychiatrists as having a personalit

Case 2. Ms. B was a 39-year-old woman from a disadvantaged ethnic group. She was moderately obese, had been separated, had never had any children, and had attended college but was now doing work markedly below the level for which her training qualified her. During the structured interview she gave almost no positive responses to questions directed at eliciting psychiatric symptoms.

Ms. B was extremely helpful and cooperative; she was also friendly and intact and acted quite appropriately. Her home was nicely furnished and well kept. When questioned about her marriage, she said that her husband had been "crazy jealous" and she had had to leave him several years before. She had had a miscarriage while married. Before her marriage and at the time of the study she was having an affair with a married man. As she proceeded to talk of her affair, she became progressively more depressed looking and finally started crying. When it was brought to her attention that she was crying she denied it. She terminated the interview after 45 minutes, saying that she had just remembered another appointment. She quickly composed herself and was smiling again as the interviewer left.

How can one evaluate this case? The further Ms. B was questioned, the more difficulties as well as positive strengths emerged. It is reasonable to assume that more pathology would have emerged with further interviewing. It is clear that a great deal of information was revealed in the relatively brief clinical interview, but was the information sufficient to warrant a change in the diagnostic impression? Three psychiatrists reviewed the data and concurred that a psychiatric diagnosis was indicated. Structured interviewing alone had not led to a psychiatric diagnosis. The signs of depression elicited in the clinical interview are consistent with the obesity previously noted. There were signs of many ego assets in this woman, along with decided psychopathology. The two existed side by side without the emergence of symptoms strong enough to propel the subject to seek help.

In the first two cases significant but well defended pathology emerged with the use of a clinical interview. In the following case the clinical interview resulted in changing the evaluation from a psychiatric case to "not a psychiatric case."

Case 3. Mr. C was a 61-year-old man from a disadvantaged ethnic group. The structured interview revealed evidence of depression, anxiety, alcoholism, and psychophysiological symptoms and the fact that Mr. C was taking tranquilizers. He was rated a "case." The clinical examination did not rule out psychopathology, but it did reveal such a high degree of adaptive functioning that a rating based on the subject's psychopathology alone is misleading.

Mr. C had grown up in an agricultural setting. He had always been anxious and fearful and came to New York City hoping to rid himself of the anxiety. He went to college also hoping to make himself secure and less frightened. He got a job in a large corporation and, again out of anxiety, pushed himself. He achieved considerable economic, occupational, and social success. During the time of his three structured interviews he was in a crisis on his job. He had recently been promoted and was involved in "political" and administrative tasks that were unlike his previous technical duties and caused him considerable anxiety. His drinking, depression, and anxiety had been with him all along but were intensified by recent events. His family physician had given him some mild tranquilizers.

He appeared to have a good relationship with his wife and family. He and his wife had discussed her feelings about their children having left home and what they should do. They decided to take in two foster children, whom they both enjoyed. He had found his structured interviews thought-provoking and helpful. He said he had gotten some insight into his problems when he started to think about some of the questions raised in the interviews. He discussed with the interviewer the possibility of entering therapy. In general, he appeared to the interviewer to be a much more alive and vital person than Mr. A and Ms. B, who had admitted to little psychopathology.

CONCLUSIONS

We selected subjects for clinical evaluation partially on the basis that the protocol of the structured interview presented problems in evaluation. Because of the way the subjects were selected, the finding that 6 out of 8 cases required a change in diagnosis does not support the hypothesis that structured and clinical interviews yield essentially dissimilar results. On the other hand, congruent evaluation in the 8 would have been strong support for the hypothesis that structured and clinical interviews result in essentially the same findings.

Two subjects misinterpreted questions in the structured interviews, and the full extent of one subject's anxiety was not revealed in the structured interview. One would expect some subjects to fall into these two categories. Adding probes to some questions might correct for those "errors" resulting from structured interviews.

For other respondents such as the three described in detail above, it is doubtful that improving a structured interview would be sufficient to detect either the subtle signs of pathology exhibited in the clinical interview or the full panoply of positive strengths and human warmth that discount other signs of pathology. In terms of making a final diagnostic evaluation, the clinical interviews also fall short. The cases described here may represent a group of individuals in the community who range from exaggerated but psychologically normal character types to well-compensated personality disorders. They rarely seek treatment, often experience little subjective distress, and establish a stable equilibrium in which mild psychopathology is balanced by strong inner resources and an ability to cope. It is questionable whether conventional psychiatric diagnosis applies in such instances where pathology and health have established a working symbiosis.

Beiser (9) has considered the problems in evaluation that are raised by this middle-range group. He stated, "The more assets a person displays the less likely he is to effect the kinds of negative maladaptations, which we have come to think of as psychiatric disorder, when confronted with stress. This is the quantitative aspect of the relationship between 'assets' and 'liabilities.' Different patternings of this relationship should also emerge, and should enable us to construct new

typologies to describe the kinds of adaptation which fall between optimal functioning and frank psychiatric disorder." (9, p. 250)

We agree with Beiser that a new typology is required to categorize nonpatients in the community who are in the middle range between frank psychiatric disorder and optimal mental health. Structured and clinical interviews yield similar findings when there is definite psychopathology or definite signs of health, but our study suggests that for some respondents in the middle range between health and sickness, the two interviews did not yield similar findings. Greater congruence in evaluation might be achieved by improvements in systems of typology.

Some Determinants of Maternal Attachment

BY GAIL H. PETERSON, M.S.S.W., AND LEWIS E. MEHL, M.D.

The authors conducted prenatal interviews and behavior observation sessions with 46 families in which the woman was pregnant. These families were again interviewed and observed 7 days, 1 month, 2 months, and 6 months after the child was born. The authors found that the most significant variable predicting the variance of maternal attachment was the length of separation of mother and infant: less separation was associated with greater attachment. The next most significant variable was birth experience, followed in importance by the length of labor and prenatal attitudes and expectations.

MOTHER-INFANT INTERACTION has received increasing attention in recent years (1, 2), along with the beginnings of the elucidation of some determinants of maternal attachment (3–5). Ainsworth (6) reviewed infant behavior patterns that seemed characteristic of attachment.

Kennell and associates (7) indicated that a unique period of special sensitivity for bonding may exist immediately after delivery. Rosenblatt (8) presented animal studies indicating that the onset of maternal behavior is based on hormonal secretions and that the postpartum maintenance of maternal behavior depends chiefly on the stimulation that the mother receives from her young. Rosenblatt (9) and Bronfenbrenner (10) presented evidence that disruption of the natural course of animal behaviors either before or immediately after delivery has deleterious effects on maternal behavior. Bronfenbrenner (10) also proposed that a critical period exists for the organization and consolidation of maternal behavior.

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Ms. Peterson is Coordinator of Family Research and Dr. Mehl is Director of Research, Center for Research on Birth and Human Development, Berkeley, Calif. Address reprint requests to Dr. Mehl at 2340 Ward St., Suite 105, Berkeley, Calif. 94705.

The authors acknowledge grant support from the Boy's Town Research Center, Stanford University, Stanford, Calif., through a grant to P. Herbert Leiderman, M.D., whose help during the planning and data collection phases of this work is also appreciated. The support of the Wisconsin Psychiatric Institute, Madison, Wis., and the American Foundation for Maternal and Child Health, New York, N.Y., is also acknowledged, as is the help of William McKinney, M.D., Barbara Brockway, Ph.D., Doris Haire, D.M.S., and Lewis Leavitt, M.D. The opinions expressed in this paper are those of the authors and not necessarily those of their consultants or funding sources.

Animal (11, 12) and human (13) studies have provided evidence that bonding occurs through early maternal-infant proximal body contact (skin-to-skin for the human). Behavioral differences have been found in the quality of the mother-infant relationship between human mothers permitted as little as half an hour of skin-to-skin contact followed by 12 hours of separation compared with mothers not permitted this initial contact (5, 7, 13). These effects have held for up to 1 year. Greenberg and associates (14) found more confidence and responsiveness to the infant among mothers permitted more contact with their full-term newborns than control subjects. Rose and associates (15) and Kennell and Rolnick (16) noted the long-term consequences of brief illnesses and perturbations of mother-infant relationships during the first 2 days of life.

In a previous study of the same group of families to be reported on here, Peterson and associates (17) found that the most important predictor variable in determining father attachment was the father's degree of participation in the birth process and his subjective report of the birth experience. In this research we attempted to quantitate the relative effect of a number of birth-related variables on the development of maternal attachment and to consider the implications of these findings for intervention with mothers and families at risk.

METHOD

Subject Selection

We selected 46 families who were not from any ethnic minority and who had middle- or upper-class socioeconomic backgrounds. For purposes of intragroup as well as intergroup comparisons, we subdivided the families into three groups: those in which the woman experienced natural childbirth without anesthesia in the hospital (N=21), those in which the woman experienced natural childbirth without anesthesia in her own home (N=13), and those in which the woman experienced delivery under anesthesia in the hospital (N=12).

The 46 families were drawn from three sources: patients of an obstetrician in private practice in Palo Alto, patients at the Stanford University Obstetrics and Gynecology Clinic, and clients of midwives of the Santa Cruz Birth Center. (The activities of this group of midwives and statistics on their work have been de-

0002-953X/78/0010-1168$0.55 © 1978 American Psychiatric Association

scribed elsewhere [18, 19].) The names of women interested in participating in this study were obtained from these three sources, and the women were contacted by telephone. The details, protocols, risks, benefits, and purposes of the study were explained and consent was obtained for an initial interview. At the initial interview these issues were again discussed. Anonymity was assured, subjects were told that they had the right to withdraw from the study at any time, and consent to proceed was obtained.

Procedure

The families were interviewed between the 6th and 8th month of the woman's pregnancy. The woman was asked about her desire for the pregnancy and the baby, her projected plans for taking care of the infant (including what social values she would teach, how much emotional nurturing she would provide, and how much of a time commitment it would require), her projected level of emotional satisfaction with the baby and her current level of satisfaction with the pregnancy, her opinion of the importance of the mother to the child as an infant, her expectations for the delivery, her level of psychological awareness of the needs of infancy, the amount of involvement planned for the father at delivery, her expectations of how the child would change her life, her attitudes about feeding an infant, and her projected confidence in herself as a mother. Discrepancies between observed behavior with the children in the home and plans for the new child were noted, along with disagreement between the marital partners. Each of the factors was scored, and the total score represented a prenatal attitude score. We felt that high scores indicated ease of attachment of the mother with her infant. Questions were also asked about behavior with any other children and the family's sociodemographic status.

The mother's behavior during labor and delivery was observed and recorded, as was the length of maternal-infant contact following delivery. After delivery, the mother was asked about her emotion satisfaction with the delivery and her feelings about her child and the birth. A birth experience score was developed on the basis of the mother's statements about delivery, her behavior during labor and delivery, her immediate reaction to her newborn, the degree of father involvement, the amount of maternal-infant contact sought after postpartum affect (e.g., elation, depression) was evident, and observed and reported behavior of the mother with the infant. High birth experience scores indicated that birth was a positive experience for the mother, that she was an active participant in the delivery, and that she sought and maintained (to the extent possible) close interaction with the infant.

Fathers and mothers were interviewed again, usually during the first week after delivery and 1, 2, 4, and 6 months later. During these sessions the mother was asked questions about her feelings of closeness to the infant and her feeling that the baby was hers, her caretaking behavior, her time involvement with the infant, her confidence in her ability to care for the baby, her feelings about caring for the infant in the middle of the night, her behavior in comforting the baby when she cried, and her feelings about the baby's motherhood, and the work of caretaking.

Discrepancies between reported and observed behavior were noted along with discrepancies between the mother's report and the reports of others. The level of agreement between the couple was noted. The behavior of the mother was recorded in a structured fashion. From these factors, an attachment score was developed. A high attachment score indicated that 1) the mother felt the baby was hers soon after delivery, 2) she was confident in caring for her infant, 3) she sought and maintained close contact with the infant for a high percentage of the available time, 4) she was confident caring for the infant in the middle of the night without excessive resentment or anger directed at the infant, 5) she responded to the infant when he or she cried, usually knowing what the cry was a request for, 6) not letting the baby cry for more than 1–2 minutes, 7) she felt reasonably happy and satisfied with the infant and with motherhood, expressing more positive feelings than negative feelings in general, 8) she related easily with her infant during the interview, holding him or her closely on occasion and comforting the infant when he or she cried, and 8) others agreed with the mother's assessment of her behavior.

With the exception of the interview in the immediate delivery, all of the interviews were conducted in the family's home. The interview team usually consisted of one interviewer who knew what kind of information the family had participated in and who had developed a high degree of rapport with the family and a second individual who did not and was present to make additional observations. On a random basis, individuals would not have foreknowledge of the family coming for research interview. This was usually done once for each family.

Data Analysis

Data were coded from recorded tapes of the interviews by three individuals, at least two of whom did not know the history of the couple. All of the individuals coded together until agreement between them reached 85%. Then every 10th tape was coded by two individuals to assure that interobserver reliability was above 85%.

Variables included in the data analysis were race, education, amount of analgesia/anesthesia, duration of mother-infant separation in the first 72 hours after delivery, length of labor, birth weight, time from delivery to the first extended feeding contact, participation in birth environment, and a disappointment score (scored with 0 for the woman who had the kind of delivery planned and 1–5 for the number of steps away from the kind of delivery planned). Positive separation scores indicated decreasing amounts of mother-infant interaction.

Each group was analyzed separately using stepwise forward-directed multiple regression analysis with a

inclusion criterion of $p<.10$ and an exclusion criterion of $p>.12$. We used the Stepreg 1-Statjob program on the Univac 1101 computer of the Madison Academic Computing Center. Variables were added to the regression according to their order of significance in contributing to their increase in the coefficient of determination until no more variables met the inclusion criteria. The program was constructed to select the initial variable as the one that would make the most significant prediction. Then the entire group was analyzed.

Our original biases were that the amount of analgesia/anesthesia, amount of maternal-infant separation, and birth environment would be the most important variables. Of these, only separation was found to be important. From a bias coding, individual interviewers' preferences did not seem to affect the results. The study was designed to assess the impact of pregnancy and birth-related variables on maternal attachment and does not consider the effect of infant variables or the mother's own early experience and parenting.

RESULTS

For the entire sample (N=46), the most significant variable predicting the variance of maternal attachment was the amount of maternal-infant separation: less separation correlated with greater attachment (partial correlation coefficient $[r_p]=.708$, significance of the increase in the regression prediction $[p\Delta r^2]<.00009$). This was followed in significance by birth experience ($r_p=.617$, $p\Delta r^2<.00009$), length of labor ($r_p=.319$, $p\Delta r^2=.0371$) (longer labors were associated with greater attachment), and prenatal attitude ($r_p=.300$, $p\Delta r^2=.0504$).

Sixty-nine percent of the variance of maternal attachment was predicted ($F=22.99$, $p<.00009$). This left 31% of the variance to be accounted for by the unmeasured factors, including infant variables and the mother's own early experience. For the subgroup of families in which the woman experienced delivery in the hospital with anesthesia, only the disappointment factor was predictive of subsequent maternal attachment ($r_p=.520$, $p\Delta r^2=.470$). This factor presumably related to the differences between couples who planned a natural or a home birth compared with those who planned a hospital delivery with anesthesia. We concluded that preparation and commitment to a delivery style in which greater personal control and parent involvement was possible increased attachment even when those plans could not be realized. The mean attachment scores of couples planning nonanesthetized deliveries who then had anesthesia were closer to the mean scores of those who planned to use anesthesia, although they were somewhat higher. We concluded that prenatal preparation had a positive effect on attachment even when plans were not realized and that it more than offset any theoretical negative effects of parental guilt feelings for not actually having the type of delivery planned. This disappointment factor accounted for 27% of the variance.

For the group planning natural childbirth in the hospital, the birth experience was the most important variable in predicting maternal attachment ($r_p=.743$, $p\Delta r^2=.0015$), followed by length of labor (longer labors were associated with greater attachment) ($r_p=.730$, $p\Delta r^2=.0020$), and maternal-infant separation (less separation was associated with greater attachment) ($r_p=-.465$, $p\Delta r^2=.0808$). Sixty-two percent of the variance of maternal attachment was predicted by these three variables ($F=21.25$, $p=.0005$), leaving 38% of the variance predicted by variables not measured.

For the group planning home birth, the birth experience was the only significant predictor variable ($r_p=.697$, $p\Delta r^2=.0056$), with 49% of the variance predicted, leaving 51% unaccounted for. There was no maternal-infant separation in this group, so this did not appear in the regression equation.

The case studies reported below emphasize the interaction of the variables discussed. In all of these cases, the contribution of variables other than the ones we studied were such that one would expect the development of an optimal mother-infant bond.

CASE REPORTS

Case 1. Ms. A, a 26-year-old woman who was employed part-time as a map drawer planned a home birth. Her husband was an anthropologist. Their first child, age 3, had been born without analgesia/anesthesia in a local hospital with the father present.

Ms. A delivered a girl on Christmas day at home; she experienced no separation from her family. When interviewed 3 days after the birth, she expressed the feeling that she was emotionally closer to this baby than she had been to her first child at the same age. She felt no postpartum depression with this delivery, although she had with her first. She attributed her immediate sense of attachment to this second child to the fact that she could hold, nurse, and sleep with her baby immediately after she was born. She said she was able to get more rest in her home than in the hospital and felt that she had healed more rapidly in her home surrounded by helping family members and friends rather than by nurses.

Case 2. Ms. B was a 28-year-old woman who was employed full-time as an airline ticket agent. Her husband worked full-time as an airline machinist. They had a 2-year-old son. Ms. B expected to make use of anesthesia in labor and delivery with this child as she had with her first and expected to return to work full-time when her newborn reached 3 months of age.

When interviewed after the delivery, Ms. B reported that she had not been able to take anesthesia because she did not get to the hospital soon enough. She reported feeling very surprised at her enjoyment of the birth process and expressed the feeling that seeing and feeling her baby being born was a very positive and emotionally strengthening experience for her. She was surprised at how much actually seeing and feeling the birth process meant to her. She reported having a great deal of faith in herself after the birth of this child, her second son, and she was grateful for the unplanned accident of a natural birth.

She held her baby for half an hour after the delivery, after which she experienced a 16-hour separation from her newborn. She said she felt emotionally closer to this baby by the end of 24 hours—sooner than for her first child, from whom she had experienced a greater separation. One month after the delivery she was considering the possibility of part-time work to facilitate breast feeding. At 6 months she was still breast feeding and working part-time.

Case 3. Ms. C was a 25-year-old librarian expecting her first child. Her husband was a graphic artist. Both wanted a home delivery. Due to a prolonged labor and uterine inertia, however, Ms. C delivered in a hospital. She had a forceps delivery and received epidural anesthesia; for 5 days she was separated from her newborn most of the time.

When interviewed soon after delivery, 1 week after delivery, and 1 month after delivery, Ms. C expressed feeling that she did not know her baby very well, that she was confused as to what to do with the newborn, and that she was helpless. She experienced a great deal of depression for the month after the delivery and felt in general less confident about motherhood than she had anticipated. She said it took her longer than she had anticipated to get to know her baby and that the baby cried more than other babies. She also said that she felt her baby was insecure during the first month, which she believed was due to the lengthy separation they had experienced in the hospital. She described the separation as traumatic for her and said she had been prone to many crying spells during this time. She described motherhood as "very trying."

In general, Ms. C experienced the birth process as ego deflating, traumatic, and lonely. She appeared to compensate for her negative experience by adopting an attitude of faith in fate and in her religion.

Case 4. Ms. D was a 32-year-old woman who taught tennis part-time. Her husband was a lawyer. They had a 3-year-old daughter. She planned a hospital delivery with epidural anesthesia, as she had had with her first child. The father planned to be present.

Ms. D delivered her second child in a hospital under epidural anesthesia for both labor and delivery. As she had with her first child, she experienced a separation from her newborn for approximately 18 hours the first day, 18 hours the second day, and 18 hours the third day after delivery.

She described the childbirth experience as very unpleasant but was grateful that this labor had been very short (4 hours). In her interview shortly after delivery she expressed the feeling that she was as close to this son as she had been to her daughter at the same age—1 week. She said she did not know either of them very well at this point and consequently did not feel they were totally hers yet. When interviewed 1 month later she again expressed the feeling that she did not really know her baby yet and did not feel it was really hers. She still felt the baby to be a stranger in the house. However, she felt that closeness would grow as time went on, as it had with her first child. She also stated that because her daughter had been her first child, she still felt closer to her than to her new baby.

DISCUSSION

The findings reported here emphasize the importance of the actual birth experience as an influence on maternal attachment. From this we would [illegible] model for maternal attachment similar to [illegible] of Bronfenbrenner (10) and Klaus and Kennell (3). Maternal attachment is dependent on many f[illegible]. We hypothesize that the factors operative prenatally along with hormonal influences aid in the deve[illegible]ment of maternal behavior, which is organized by birth experience and then consolidated by the presence of the infant and the interaction of mother and infant during the immediate postpartum period. From the results of this study, it would appear that birth experience and separation are important variables. Appendix 1 lists the stages in the development of attachment, along with the influences, disruptions, and types of intervention possible at each step. In all stages, interventions include easy access to family therapy and [illegible] mental health services, home health support for families needing health services, and public education programs.

We envision the mother's experience during labor and delivery as a crucial transition point in the development of maternal attachment—a period of crucial stress or crisis. We hypothesize that the unfolding intrapsychic events of labor constitute the organization of all prenatal influences into a series of distinctive maternal behaviors and affectional beliefs. These psychic associations with labor and delivery will affect the process, which, finally, is consolidated by the presence of the baby and the responsiveness of the baby to the mother's behaviors and feelings. The presence of the baby provides the concrete reality to the fantasized object and, as such, both releases and concretizes maternal attachment.

Bronfenbrenner (10) noted that when the behavior of an animal is disrupted before consolidation has begun, the behavior is absent from the animal's repertoire. When behavior is disrupted during but before completion of consolidation, the behavior will be expressed when the animal is placed in a situation requiring the emission of that behavior, but either inappropriately high frequency or with an inappropriately low threshold. We hypothesize that this effect explains the high occurrence of battered/neglected child syndrome and the overprotected child syndrome among the parents of premature infants (5, 13, 15). The separation of premature infants is extreme. We speculate that these varieties of these conditions may operate in the parents of full-term infants whose behavior has been disrupted before or during consolidation. Therefore the sensitive period that Klaus (13) argued for can be seen as the period of consolidation of behavior. Subsequent to this period, behavior can still be integrated, but it is a more difficult task and does not have the natural mechanisms of the species assisting the process.

During the birth process, the mother is [illegible] vulnerable; she is opening up both physically and mentally. Separation from her infant following delivery may act as a powerful punishment for [illegible] behavior, but the presence of the baby may [illegible]

erful reward. This may explain the beneficial effects of a positive birth experience on maternal self-esteem (20) and on the spontaneous resolution of neurotic conflicts (19). Subsequent experience, unexpected or changing life conditions, and unconscious motives may also have vital influences on the attitudes and values of parents and on the development of attachment.

The assimilation of the baby into the family is affected by projective identification (21), which may be an explanatory factor for the development of psychopathology in a family member (22). The physical presence of the baby diminishes this effect by permitting reality testing. Separation maintains the infant in the status of a fantasy object—the longer the separation, the greater the tendency toward projection.

A negative birth experience in which fear and pain and discomfort predominate may have far-reaching consequences. Fear and pain breed resentment and hostility toward the object associated with the fear, pain, and discomfort. Fathers, in a sense, may act as affect meters for this process. We have heard fathers expressing jealousy and hostility toward their infants because of the pain and discomfort their wives experienced in childbirth. We have observed this ambivalence persisting in the relationship of both parents with the infant. Such a phenomenon has also been observed in clinical psychiatric practice. This is in sharp contrast to fathers and mothers who perceive birth as a positive emotional experience.

APPENDIX 1
Stages in the Development of Attachment

I. Birth of Mother
  A. Influences
    1. Experience of being nurtured
  B. Disruptions
    1. Genetic factors affecting intelligence, etc.
    2. Caretaker-infant separation
  C. Opportunities for intervention
    1. Prevention of maternal-infant separation
    2. Active social work and nursing intervention for families at risk
    3. Interventions discussed in stages V and VI

II. Childhood experiences
  A. Influences
    1. Parents' development of psychological difficulties with assumption of parental role
    2. Parents' provision of appropriate role models
    3. Sociocultural identification and learning regarding role-specific behavior
  B. Disruptions
    1. Discontinuity in caretaking
    2. Family dynamics
    3. Family crises
  C. Opportunities for intervention
    1. Inclusion of education regarding childbirth in high school and grade school curricula
    2. Involvement of siblings in childbirth whenever feasible
    3. Easy access to mental health services and paraprofessionals in the community for family therapy
    4. Provision of adequate role models
    5. Social intervention (e.g., in the case of poverty)

III. Marriage before children
  A. Influences
    1. Relationship with father of child
  B. Disruptions
    1. Marital conflict
  C. Opportunities for intervention
    1. Couple therapy
    2. Family planning services
IV. Conception and pregnancy
  A. Influences
    1. Desire for pregnancy
    2. Prenatal attitudes toward the pregnancy, childbirth, and the infant
  B. Disruptions
    1. Unwanted pregnancy
    2. Complications of pregnancy
    3. Family crises
  C. Opportunities for intervention
    1. Social work and nursing support for families with complications
    2. Childbirth preparation classes providing new role models for parenting
    3. Provision of information regarding alternatives to childbirth
V. Birth
  A. Influences
    1. Birth experiences
    2. Length of labor
  B. Disruptions
    1. Environmental disruption
  C. Opportunities for intervention
    1. Support and encouragement for low-risk mothers choosing alternative birth environments
    2. Avoidance of disruption of naturally occurring behavior of parents during labor
    3. Provision of support services for high-risk parents
    4. Avoidance of unnecessary obstetrical intervention
    5. Facilitation of friends' and relatives' involvement in labor
VI. Early postpartum period
  A. Influences
    1. Infant's behavior
    2. Father's development of attachment
  B. Disruptions
    1. Maternal-infant separation
    2. Environmental disruption
  C. Opportunities for intervention
    1. Avoidance of maternal-infant and family-infant separation
    2. Avoidance of disruption of naturally occurring parental behavior
    3. Teaching new behaviors and providing new role models for parents at risk
    4. Aggressive community services and support for families at risk
    5. Involving parents in the care of sick neonates

Am J Psychiatry 135:10, October 1978

The Role of Infant Observation in Child Psychiatry Training

BY GEORGE W. GREENMAN, M.D., RONALD BENSON, M.D., LEXINGTON GRAPENTINE, M.D., CECILY LEGG, M.S.W., AND IVAN SHERICK, PH.D.

The authors discuss the role of infant observation in the training of child psychiatrists, emphasizing the overriding importance of the subtle but crucial interactions in the mother-infant relationship. Infant observation is valuable in preparing the student as an observer of behavior, and developmental concepts are taught and learned more easily in programs that provide opportunities for observing normal infants. The infant study program in the Department of Psychiatry of the University of Michigan Medical Center is presented as a model.

BECAUSE OF the numerous reprint requests for articles on infant and early childhood research published in the *Journal of the American Academy of Child Psychiatry*, the editors of that journal published a collection of many of them, entitled (provocatively) *Infant Psychiatry, A New Synthesis*. The editors proposed a new subspecialty of infant psychiatry and argued that child psychiatry training is a logical starting place for such a program (1). An upsurge of interest in the first year of life is evident from the large number of recent books and articles dealing with various aspects of infancy (2–6).

Selma Fraiberg addressed the problem of who should provide diagnostic assessment and treatment to infants and their families (unpublished manuscript). She advocates a subspecialty in infant mental health for all professionals who serve babies and their parents, including psychiatrists, pediatricians, pediatric and psychiatric nurses, psychologists, and social workers.

One of the possible reasons for the call for infant psychiatrists is that most child psychiatry training programs pay scant attention to infancy (7). At best, normal and pathological infant development are presented in didactic lectures. The student rarely sees a normal baby and even more rarely is assigned an infant for evaluation or treatment.

DEVELOPMENT OF AN INFANT OBSERVATION PROGRAM

Because of the need for more experience with infants and their families, infant observation became part of the two-year program in child and adolescent psychiatry at the University of Michigan in 1974. Couples having their first baby are invited to participate in the program on the basis of their own interest, the probability of a stable family situation, the likelihood of at least a year's residence in the area, a delivery date in September, and the absence of overt psychopathology. Preference is given to first-born infants for several reasons. The student has the opportunity to observe and comprehend, in its incipiency, the complex phenomenon of parenting. Inclusion of only single-child families serves as a means of limiting somewhat the number of variables (always large) in the study population. More pragmatically, the single-child family tends to have greater freedom and flexibility for scheduling appointments to synchronize with the trainee's limited availability. An additional advantage in the use of single-child families is that, for beginning observers, it is generally easier to carry out an infant observation without the distractions provided by older siblings. Stable couples give the resident a greater opportunity to observe the unfolding of a relatively normal family and, on a more practical level, tend to be home when home visits are scheduled and to keep appointments for office visits. The expectant couples are referred to us by other participants in the program or are recruited by senior staff in contacts with childbirth preparation classes, such as Lamaze.

PRENATAL AND PERINATAL PERIOD

Each child psychiatry fellow is assigned a family in July at the beginning of his second year of child psychiatric training. He is asked to interview the couple separately and conjointly in the weeks before the baby is born, obtaining a detailed personal history from husband and wife. In addition, an attempt is made during

This is a revised and combined version of three papers presented at the 129th annual meeting of the American Psychiatric Association, Miami, Fla., May 10–14, 1976.

The authors are with the Child Analytic Study Program, University of Michigan Medical Center, Children's Psychiatric Hospital, Ann Arbor, Mich. 48109, where Dr. Greenman is Lecturer in Psychiatry; Dr. Benson is Clinical Associate Professor of Psychiatry and Director, Outpatient Program; Dr. Grapentine is Instructor of Psychiatry; Miss Legg is Lecturer in Mental Health; and Dr. Sherick is Clinical Assistant Professor of Psychology in Psychiatry.

the interviews to gather data concerning the myriad hopes, expectations, and worries surrounding the unborn child. These parental fantasies, both positive and negative, give the resident his first revealing glimpse of the elusive ethos into which the infant will be born. We have found, for example, that important expectations exist regarding the sex, intelligence, motor ability, and physical attractiveness of the child. In the months to come, this fantasy material can be compared with the realities of the young child's endowment. The attitudinal changes of the parents in the face of this reality can be followed. Often, from the earliest days parents attempt to shape the child to fit their conscious and unconscious expectations. The student is in a good position to learn and to intervene if indicated because he knows the prebirth fantasies.

The resident is encouraged to obtain permission to be present at the birth. The delivery experience, which usually includes the fathers, affords the resident a unique opportunity to observe the earliest mother-child-father interactions. At the same time, he can be aware of any complications in the birth process and can assess the newborn along several measures, from the Apgar rating to visual tracking. Also, the resident's knowledge of obstetrics is occasionally a source of support to the father. Most important, however, is the direct observation of the initial dialogue between mother and child. The mother's affective state and her comments about the infant can be most revealing, and the newborn's responses when the mother holds him can be an important index of their future interactions (8).

While they are still in the hospital, the mother and infant are visited several times. This gives the resident a chance to explore in depth the mother's attitudes toward the newborn and to contrast them with her earlier wishes and fantasies. At breast or bottle the child is observed in the mother's care, and many of her basic nurturing skills come to light. The resident notes the baby's beginning ability to integrate the complex physiological functions of sucking, swallowing, and breathing that comprise nursing. In the nursery or at the mother's bedside the baby can be directly examined and held by the trainee for the first time, an intimate contact that may be a new and important experience for the trainee. He acquires a "feel" for his subject, which adds to his ability to assess temperament, alertness, and the infant's ability to mold. He can observe how primitive and yet how highly organized is the newborn's behavior. Frustration tolerance, output of activity, contrasts between states of alert inactivity and waking activity (9), and many other characteristics are sometimes precursors of later behavior.

In September, usually soon after the baby's birth, the child psychiatry fellow is joined by a second team member, a nurse enrolled in the master's degree program in parent and child nursing at the University of Michigan School of Nursing. The nurses are on a semester system and therefore miss the beginning and end of the family's year-long participation.

HOME AND OFFICE VISITS

About 2 weeks after delivery, the child psychiatry fellow and nurse make a home visit at a time when the father can be present. This offers both trainees their first opportunity to observe the complete family in its natural surroundings, with the rich variations offered by the ever-changing circumstances of family life, and provides a further chance to sharpen their skills as participant observers. The observers are alerted to note the mother's affective tone, skill, and comfort as she feeds, bathes, diapers, and interacts with the baby. The baby's responses are noted in similar detail. With the mother's consent and approval, each observer holds the baby and makes observations of his social responsiveness, muscle tone, and molding. This routine, to that of the observer. In addition, they ask the parents about the behavioral patterns of the infant and about their attitudes and behavior toward this new family member. The home visit also allows the team to make direct observations of the nature of the fathering and to take a close look at the quality of the interactions between the mother and the father concerning their baby.

The program is devised for teaching rather than service. However, parents occasionally seek to use the study situations to further their knowledge of child development or to seek reassurance on their parenting styles. Appropriate response is made to such requests. Although the observers are not looking for problem situations, when a possible developmental hazard is noted it is shared with the parents.

Home visits continue at monthly intervals throughout the year. The visits are required for the nurse trainee, elective for the child psychiatry fellow, depending on the time available in his crowded schedule.

Each month, after the initial home visit, the mother, father (if he can come), and baby visit the office. An updated history is taken, focusing on such issues as sleeping and feeding patterns, preferred styles of parental interaction with the child, and the infant's increasing awareness of the world around him.

Formal developmental testing is also done (10). The child psychiatry fellow is responsible for testing procedure. He now becomes familiar with the "tools of the trade" of infant developmental assessment—bell, colored ring, wooden cubes—and learns which tests are appropriate for the child's age. Among other things, he tests for the presence of neonatal reflexes and learns when a positive response should no longer be expected. In general, he becomes adept at eliciting and understanding the neurophysiological signs of growth. The test procedure is videotaped and can be followed simultaneously by other trainees from a distant monitor. Thus, other residents gain first-hand look at more than one infant. In this way they begin to see the variations among infants in function and temperament and come to appreciate the norms and regularities in the unfolding of each infant's mental and emotional development. In addition, the trainee

ability to observe accurately and discuss these observations is heightened. As the infant matures the test data include information about such complex phenomena as, for example, his ability to relate to human objects. The attitude of the child toward complete strangers and toward the tester can be documented, and changes with time in the young child's response to being out of direct contact with the mother can be assessed. Perceptual ability, gross and fine motor control, and cognitive style can also be assessed early and followed in detail over several months.

The nurse is a nonparticipant observer during the office visits. The nurse can note and record complex interactions between the mother, infant, child psychiatry fellow, and video technician during the developmental testing that might otherwise escape notice. For example, the mother's reactions to the examiner's "taking over" and managing the baby during the testing are informative. The child psychiatry fellow, as a beginner in infant developmental testing, may be too involved in administering the test to be attuned to these interactions.

Before the monthly office visits, the resident-nurse teams meet with one or more senior staff members for a briefing on the administration of the infant tests and a discussion of expectable developmental phenomena for infants of a particular age. The babies are all close to the same age, so normal variation is emphasized. If the child psychiatry fellow has not made the home visit two weeks earlier, he has the opportunity to read the nurse's written report before the office visit. After the families are seen, the students and teachers reconvene to discuss the results of the morning's observation and to review the videotape, if desirable. Office space suitable for infant observation is limited, so a maximum of three infant-parent pairs is seen on any one morning. Supervision is primarily accomplished in these group briefing and debriefing sessions. Each fellow is assigned an individual supervisor with whom he can meet if a problem arises that cannot be dealt with during the group supervision.

DATA RECORDING

Another facet of the infant study experience is documentation of data. Following each contact, the trainee writes a report outlining the important observations. At the end of the year, each resident gathers together his knowledge of the child he has been following into an infant developmental profile, a modification of Ernest Freud's baby profile (11). The profile requires a detailed awareness of parental history, the pregnancy and perinatal period, the range of parent-child interaction, latent parental attitudes, and neurophysiologic milestones. Preparing the profile allows the resident to formulate his understanding of the infant's maturational unfolding, constitutional strengths and weaknesses, and significant environmental influences. The profile imposes on the trainee a sense of discipline in his attempt to delineate the critical forces that impinge on the first year.

Infant observation dovetailed neatly with existing opportunities for observation of normal children in our toddler groups and nursery school. A basic goal of our training program is to enhance a thorough understanding of the variations and common characteristics of normal human development. The influences and attitudes of the people comprising the environment and the elements provided through maturation are closely scrutinized. The infant observation opportunities provide the trainee with a rare opportunity to follow, from the earliest moment, the unfolding of these maturational and environmental dimensions and to observe their manifestations and interactions.

For many child fellows, involvement with very young children is not new. Several of the residents are parents; some have come to the child psychiatry program from general practice or a residency in pediatrics, and most have dealt with infants to some degree during their medical school years or internship. What is unique in the infant study experience is the chance it affords to observe objectively essentially healthy infants over a prolonged period and to assess in detail the vicissitudes of early development of a particular child.

VIDEOTAPE USE

All office visits and many home visits are recorded on videotape. A first imperative for the use of videotape is a camera operator who is more than a technician. The camera operator must have an interest in and some basic knowledge of the psychological development of the infant. In the hands of a skillful trained video technician who is fully conversant with the aims and goals of the particular study, the video camera is an invaluable instrument for recording and collecting data that would otherwise be omitted from the record or documented only inferentially.

CASE ILLUSTRATIONS

The practical value of the infant observations in child psychiatric training can be underscored by two brief case vignettes.

Case 1. We began following John A, one of our first infants, when he was 6 weeks old. His intelligent, well-educated parents had heard about the infant study from a friend.

John grew and developed exceedingly well in all areas that we could measure. He was breast-fed and ate well; later he accepted solids readily. He was sleeping through the night consistently by 18 weeks. Motor and language development proceeded at or above the expected rate. His most characteristic trait, which charmed all who had contact with him, was his winning and frequent smile. He was a person-oriented baby, and he smiled broadly at anyone who approached,

until "stranger anxiety," which started when he was about 6 months old, made him a bit more wary.

A crisis requiring intervention by the child psychiatry fellow occurred when John was about 7 months old. Mrs. A had taken John to visit her mother in a distant state. The grandmother was described as a compulsively neat woman who would not adjust or rearrange her home for her increasingly mobile grandson. She refused to participate in John's care because he was crawling and required control. Mrs. A cut her visit short and returned home feeling dominated by John. The demands of his care seemed endless, and she felt that she had no time for herself. A few days later, her former employer called to see if she could return to work. She felt tempted but was ambivalent about leaving John in the care of a stranger. During the office visit in which the child psychiatry fellow obtained this information Mrs. A had to leave the room for about 5 minutes. The change in John was dramatic. He had been smiling joyously at every eye contact with his mother, the child psychiatry fellow, and the video cameraman to that point but quickly became somber and started looking around as if trying to locate his mother. By the time his mother returned he was fussing and, although he was comforted when she held him, he would not cooperate in the developmental testing.

The child psychiatry fellow used the above observation to underscore the intervention he now made. He told Mrs. A that he agreed with her about her continuing importance to John but empathized with her, noting how endless the process of child rearing can seem from time to time. He interpreted her desire to return to work, now that John could crawl, as being somehow an echo of her mother's attitude during the recent visit. Mrs. A recalled intense conflict with her mother about messiness, seemed to settle down, and left the office thinking in terms of a part-time job that would give her some time for herself. A month later, she had dropped the idea of returning to work and contented herself with taking some informal classes.

We believe that John's despair at discovering his mother's absence in the presence of strangers in a strange place shows that at 7 months his cognitive development had proceeded to the point at which he could clearly differentiate the strange from the familiar. He responded with anxiety when his mother left the room because of fear of the loss of the preobject, i.e., the person who reduces tensions through appropriate care. He had recognized his mother as a source of need satisfaction, and her absence evoked anxiety. Indeed, other observations indicated that John desired his mother for more than a source of tension relief, and thus his object relationships had started along the developmental line from need satisfaction to object constancy. To have been separated from her at this point in his development could have been particularly traumatic for him and might have resulted in developmental interference or more serious problems. The intervention helped to allow John's development to unfold without hindrance.

Case 2. Margaret B was conceived 6 months after the death, at age 3 weeks, of an infant born with multiple congenital anomalies. Throughout the prenatal interviews both parents made repeated references to the first baby and expressed concern about the health of the unborn infant. At delivery, Margaret was found to be fully intact, but the parents, understandably, continued to harbor latent concerns. By age 6 months, there were slight differences between Margaret's development and that of the other infants in the study of similar age. Mrs. B became overtly anxious. At this point the child psychiatry fellow made an extra home visit without a video cameraman. Parental concerns were explored and the death of the first baby was reviewed. Mrs. B tied her awareness of Margaret's slightly delayed motor milestones to her own lack of athletic abilities and implied that she wanted her daughter to be better endowed than she had been. The child psychiatry fellow reaffirmed his earlier statements about the baby's normalcy. Shortly after the home visit, Margaret achieved important milestones and the mother's anxiety waned considerably. Since that time, the parents have periodically used the child psychiatry fellow in "consultation" when questions or concerns have arisen.

In this case, the primary cause for the parental anxiety, which threatened to interfere with optimum parenting for Margaret, was the earlier birth and death of the multiply deformed child. The mother's reference to her own "unathletic" nature and some of her other comments suggest a self-concept of damage or deformity that would have been (understandably) exacerbated by the birth of a deformed baby. The supportive and expressive intervention gave the parents a chance to once again review their feelings about the first baby, to express their concerns about Margaret, and to review the objective evidence indicating Margaret's intactness.

DISCUSSION

A comprehensive discussion of the advantages to the child psychiatrist, and the adult psychiatrist for that matter, of a thorough understanding of maturation and development (see reference 12) during the first year of life by direct observation could be the subject of another paper, and a few of the most important aspects will be mentioned here (see reference 13). Near the top of any list of advantages must be the opportunity to observe that the human infant develops in a matrix of object relations and that during the first year the relationship to his mother is of overriding prominence. The importance of the infant-mother relationship is usually taught so didactically that the phrase may become meaningless. Its meaning is given immediate substance when one observes the interaction between the pair, beginning when the baby is given to the mother in the delivery room. The informed observer can see that the mother's role as the infant's first teacher begins then. The teaching may have varying qualities within the same mother-infant pair, as seen recently when a delighted young mother, who was very adept at holding, comforting, and nursing her 2-day-old baby, stopped the baby from touching his mouth, saying that it could develop into a bad habit.

The relationship is not only in terms of how the mother affects the infant. The infant's characteristics, such as sex, health, appearance, activity, and ease with which it can be comforted, can have a profound influence on the mother. The trainee is in a unique position to observe this phenomenon because of his previous knowledge of the mother's hopes, fantasies, and expectations concerning the baby. Knowledge of the mutual influences of the mother and child from birth is useful to the future child psychiatrist in assessing both

infants and children. The skill of unintrusive, nonjudgmental observation that the trainee learns in observing infants will enhance his work as a psychotherapist of children and adults.

Nearly everything that is learned in lectures, seminars, and from reading takes on new meaning when directly observed. Developmental milestones are a good example. Observing the 4-week-old infant smile in response to its mother, watching the 16- to 20-week-old's efforts to reach and grasp, noting the transfer patterns of the sitting 28-week-old, the wariness toward strangers of the 40-week-old, and the delight in locomotion of the 52-week-old, provides more powerful inducements to remembering milestones. Perhaps even more important is the opportunity to watch the precursors of mental functioning taking shape. Primitive reactions to displeasure may foretell what kinds of ego defenses the infant will use in the future (11). Earliest memory for inanimate objects can be seen when, as part of the infant test, a toy is hidden. Very early, one can see which infants are people-oriented, which are thing-oriented, and which show an even balance between the two. One can discern styles of cognitive development and the different ways by which early concept formation is achieved. The teaching and learning of all developmental concepts is enhanced by direct infant observation.

We are often asked why families volunteer to be in our program and what we give them in return. We do not offer service or advice. The answer, in general, is on multiple levels. On the surface are such motivations as the wish to cooperate in a program that helps to train doctors, the opportunity to have their baby seen (and admired) by experts, and reassurance that the baby's development will be monitored. Slightly below the surface is the desire for emotional support during the transition from being a separate entity into that ever demanding and potentially rewarding role as parent. Parents often wish, unconsciously, that participation in the program will protect their infant from disasters that have happened to family members in the past. This was illustrated in case 2.

A training program like ours is not designed to graduate infant mental health specialists; rather, it is designed to acquaint the trainee with the developmental vicissitudes of infancy. With that background, the graduate can make some interventions and knows when to refer more complicated cases.

Prediction of Imipramine Antidepressant Response by a One-Day *d*-Amphetamine Trial

BY DANIEL P. VAN KAMMEN, M.D., PH.D., AND DENNIS L. MURPHY, M.D.

This study provides additional evidence that there is a moderate association between the acute activation, euphoria, and antidepressant responses to d-*amphetamine and the antidepressant response to imipramine during a four-week trial. Comparison of the responses of 13 patients to* d-*amphetamine on two different days during a double-blind trial indicated that differences in* d-*amphetamine response are consistent, replicable characteristics of individual depressed patients. The variables of sex, diagnosis, diurnal mood variation, platelet MAO activity, and MMPI scale scores were of minimal assistance in revealing factors that might be associated with activation or antidepressant responses to* d-*amphetamine in this small patient group. The authors suggest the need for larger-scale studies in this area.*

SINCE THE tricyclic antidepressants became available in 1954 (1, 2), attempts have been made to develop criteria for their most effective clinical use (3, 4). However, only a few studies of response prediction have appeared in the literature (5). In 1971 Fawcett and Siomopoulos (6), in a study with a small number of depressed patients, reported that the antidepressant response to 1- or 2-day administration of *d*-amphetamine provided an indication of the fourth-week treatment response to tricyclic antidepressants. If a 1- or 2-day administration of a drug such as *d*-amphetamine can predict responses to antidepressant drug trials, which may otherwise require a 3- to 6-week trial, a more rational psychopharmacological approach to the treatment of depression could result, rather than present-day trial and error (7).

Although amphetamine is known to be a CNS stimulant, there is a wide variation in individual response (8–11). This study is an attempt to replicate the Fawcett and Siomopoulos findings (6) and the subsequent more extended studies by Fawcett and associates (12, 13) and also to examine some of the individual characteristics that may play a role in the response to *d*-amphetamine. We report on the self-rated effects of oral *d*-amphetamine in a group of depressed patients and compare this response with the fourth-week antidepressant response to the tricyclic antidepressant imipramine.

Revised version of a paper presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. van Kammen is Unit Chief, Section on Neuropsychopharmacology, Biological Psychiatry Branch, and Dr. Murphy is Chief, Clinical Neuropharmacology Branch, National Institute of Mental Health. The authors wish to thank the patients and nursing staff of the 3-East clinical-research unit, NIH Clinical Center, for their cooperation in the study, Jean Colison for assistance with the data analysis, and Estelle Churgin and Janice Grice for editorial and secretarial assistance.

METHOD

Subjects

Thirteen inpatients (7 women and 6 men, with a diagnosis of primary affective disorder, including 9 unipolar patients, 1 bipolar I, and 3 bipolar II depressed patients, received trials with both *d*-amphetamine and imipramine. The patients' ages ranged from 18 to 60, with a mean of 43 years. Eight additional patients (4 men and 4 women, of whom 5 were unipolar and 3 bipolar I depressives) received *d*-amphetamine trials alone. These 8 patients had all previously received a full imipramine trial before they were admitted to the NIH Clinical Center and were all considered imipramine nonresponders because they were still sufficiently depressed to require hospitalization after meeting the criterion of 3 weeks or more of treatment with imipramine in doses of 150 mg or more per day as outpatients.

All patients were voluntarily hospitalized and had signed informed consent forms before participating in the studies. They were diagnosed according to the Research Diagnostic Criteria (14) for primary affective disorder. Patients with organic brain syndrome, alcoholism, or medical illness were excluded. Unipolar patients were depressed patients without a history of mania or hypomania, while bipolar I patients were depressed patients with a history of hospitalization for mania; bipolar II patients had a history of hypomania that was not severe enough to require hospitalization for mania.

Patients were rated daily for depression and mania by the research nursing staff using the Bunney-Hamburg Rating Scale (15). The means of the depression ratings of the week before each drug protocol were taken as baseline depression ratings for that protocol. All patients had been off psychoactive drugs for at

least 15 days before any of the drug protocols and had been maintained on a controlled monoamine diet. Before each drug protocol all patients had had experience with the self-rating scales. They received identical capsules four times daily during the entire study period.

d-*Amphetamine Protocol*

Twenty-one patients went through a 7-day double-blind, placebo-controlled protocol. This consisted of oral administration at 7:25 a.m. of 30 mg of *d*-amphetamine (as the base) on 2 separate days and placebo capsules on the other 5 days. Placebo always was given on the first and last days of the protocol. In every case the 2 *d*-amphetamine days were separated by at least 2 days on placebo. For the evaluation of the subjective effects of *d*-amphetamine, the patients completed a 34-item mood and behavior self-rating scale 11 times during the protocol day between 7:15 a.m. and 9:30 p.m. (10). Groups of items covered by the scale included activation, euphoria, depressed affect, and dysphoria (10). The average of the 9:00, 10:00, and 10:30 a.m. ratings (the times of peak drug effects) was used for the evaluation of the morning drug effect. Previously reported *d*-amphetamine levels peaked around this time and correlated with behavioral responses to amphetamine (16).

The ratings from the first placebo day were always excluded from the analysis to eliminate "first-day" effects of the study. The self-ratings from the morning (9:00, 10:00, and 10:30 a.m.) were compared with those from both the afternoon (2:00 and 4:15 p.m.) and evening (7:00 and 9:30 p.m.) on the placebo days for the evaluation of a diurnal variation in depression. The self-ratings from the 4 placebo days were averaged and compared with the self-ratings from the same times on the *d*-amphetamine days. The mean of the placebo days' ratings was subtracted from the mean of the *d*-amphetamine days' ratings to determine the *d*-amphetamine response. We have previously reported that the administration of *d*-amphetamine on 2 different days induced similar behavioral responses, which permitted the use of the mean of the 2 days' responses (10). The replicability of the effects of *d*-amphetamine on the 2 days was evaluated again in this group of depressed patients.

Imipramine Inpatient Trial

Thirteen patients received a 4-week trial of imipramine during their hospitalization at NIMH, with a mean daily dose of 230 mg per day during the fourth week (range of 150–300 mg per day). Imipramine administration was preceded by 2 weeks of placebo and followed by placebo. The response was defined by comparing the means of the daily behavioral depression ratings on the fourth week with the means of the daily ratings before the onset of the imipramine trial. A change larger than 1.5 on the Bunney-Hamburg scale represented a statistically significant change and reflected a clinically significant improvement (13). Responding patients were divided into 2 groups: moderate improvement (1+) if the mean changes in depression ratings were between 1.5 and 2.5, and marked improvement (2+) when the mean response was larger than 2.5 rating units. Responses to imipramine were defined as "no change" if a mean depression rating decrease of less than 1.5 occurred. This allowed us to rank order the patients over a 3-point range. Responders and nonresponders received similar mean daily doses of imipramine in the fourth week; responders received 235±40 mg per day and nonresponders 216±67 mg per day (t=0.638, p=n.s.).

Correlation Between *d*-Amphetamine Responses and Imipramine Antidepressant Trial Response

Group	N	Correlation (τ)			
		Activation	Euphoria	Depression	Dysphoria
Women	7	.55	.55	−.65	−.22
Men	6	.64	.70	−.23	.08
Total unipolar	9	.48	.53	−.46	−.13
Unipolar women	6	.45	.45	−.60	−.15
Total	13	.61*	.61*	−.48**	.09

*p<.01.
**p<.05.

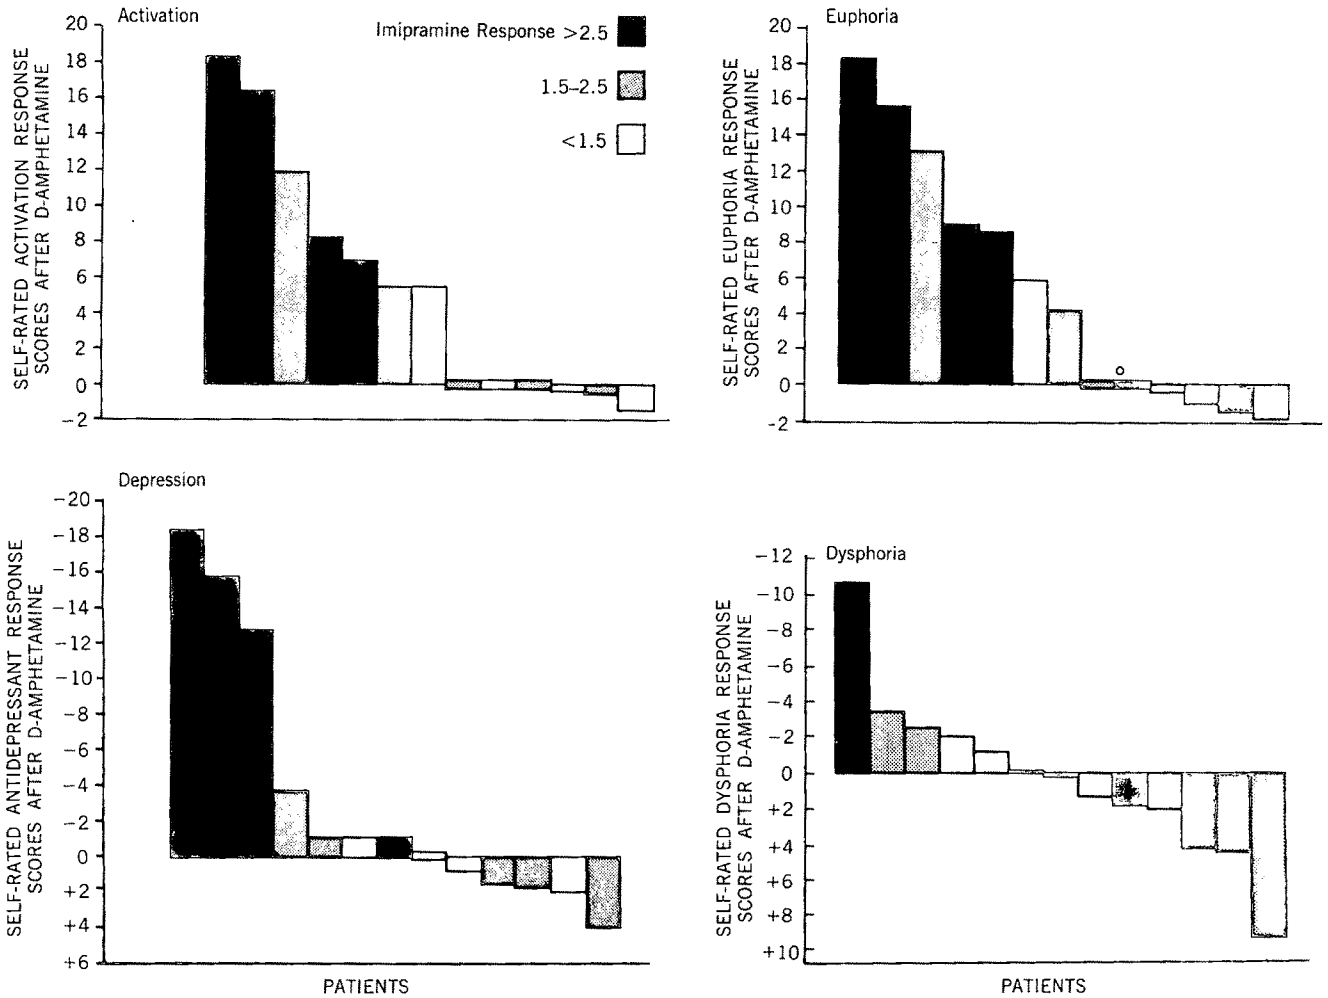
MMPI and Individual Differences in d-*Amphetamine Effects*

It has been suggested that personality factors may play a role in response to *d*-amphetamine (17–19). Twenty-one patients completed the Minnesota Multiphasic Personality Inventory (MMPI) (20). The clinical subscale scores were examined for possible correlations with the individual responses to *d*-amphetamine.

Monoamine Oxidase

Platelet monoamine oxidase (MAO) activities were evaluated against *d*-amphetamine responses. MAO platelet activity (in nmol/10^8 platelets per hour) was determined in 21 patients using blood samples obtained just before the first placebo day of the *d*-amphetamine trial, according to previously described methods (21).

Data Analysis



Spearman's (r) and Kendall's (τ) rank-order correlations were used for nonparametric data analyses. For continuous data Pearson's correlation coefficient was used. Two-tailed t tests were applied for paired and nonpaired data analyses.

RESULTS

Relationship Between d-*Amphetamine and Imipramine Responses in the Imipramine Inpatient Trial*

Significant correlations were found between the *d*-amphetamine-induced changes in activation, euphoria,

FIGURE 1
Self-Rated Change Scores of 13 Patients on Activation, Euphoria, Depression, and Dysphoria Items*

*The change scores were recorded 1½–3 hours after the oral administration of 30 mg of *d*-amphetamine in the morning. The imipramine responses were observed during the fourth week of imipramine treatment for each patient.

and depression self-ratings and the antidepressant effects of imipramine (table 1). Figure 1 shows the individual responses of these patients to *d*-amphetamine and imipramine. Patients are rank ordered according to their responses to *d*-amphetamine. In general, patients with the greatest activation, euphoria, and antidepressant responses to *d*-amphetamine also tended to improve with imipramine. There was no apparent relationship between the dysphoria responses to *d*-amphetamine and imipramine antidepressant responses.

Relationship Between d-*Amphetamine and Imipramine Responses in the Total Sample*

The *d*-amphetamine responses of the patient group that had only preadmission outpatient trials with imipramine closely resembled those of the inpatient imipramine responder group rather than those of the inpatient nonresponders (table 2). When these 8 imipramine nonresponders by history were included in the rank-order study, the previously significant correlations all became nonsignificant. Furthermore, when this entire group was divided into male, female, unipolar, and bipolar groups, almost no significant correlations were observed between the self-rated responses to *d*-amphetamine and the antidepressant responses to imipramine, although the small numbers of patients and lack of equal numbers of patients in the different sex-diagnosis categories render these comparisons unlikely to be informative. Only the euphoria self-rated response in the 7 bipolar patients correlated significantly with the antidepressant imipramine responses (Kendall's $\tau=0.65$, $p<.03$). It is of interest that the bipolar and unipolar patients exhibited other differences when intercorrelations between the subjective responses to *d*-amphetamine were examined (i.e., activation versus euphoria versus dysphoria versus antidepressant response). While the bipolar patients had no significantly intercorrelated subjective responses to *d*-amphetamine, the unipolar patients showed highly significant intercorrelated subjective re-

Range		−0.5−24.8	−3.1−19.1	1.4−12.8	−5.6−3.1

*p<.005 (comparison of imipramine inpatient responders with nonresponders).

sponses, with a strong positive correlation between activation and euphoria (r=92, p<.001) and strong negative correlations for activation and euphoria versus dysphoria (r=−.59, p<.01) and depression versus the other self-rated categories (r ranged from −.72 to −.77, p<.001).

Replicability of d-*Amphetamine Responses*

Self-rated antidepressant responses on the first and second days of *d*-amphetamine administration were significantly correlated at the time of peak drug effect (r=91, p<.001, N=19). This was also the case with the self-rated activation (r=.52, p<.05), euphoria (r=.63, p<.01), and dysphoria responses (r=.87, p<.001, two-tailed t test).

Relationship Between Diurnal Variation in Self-Rated Depression on Placebo and Response to d-*Amphetamine*

To evaluate whether circadian variations in mood would affect drug response, we examined the relationship between *d*-amphetamine responses and change of mood during the day. Differences between morning versus afternoon and morning versus evening self-rated depression on placebo were not significantly correlated with *d*-amphetamine responses in the 21 patients.

MMPI Clinical Subscales and Individual Differences in d-*Amphetamine Effects*

The depression (r=−.47), psychasthenia (r=−.48), and social introversion (r=−.46) subscales of the MMPI showed significant negative correlations with activation responses to *d*-amphetamine at the time of peak drug effect (p<.05). Dysphoria responses to *d*-amphetamine were negatively correlated with the hysteria subscale (r=−.52, p<.02). No other significant correlations were observed between the MMPI clinical scales and the subjective responses to *d*-amphetamine.

MAO and Individual Differences in d-*Amphetamine Effects*

Platelet MAO activity (mean ± SEM) for the men was 8.8±0.97 nmol/10^8 platelets per hour; the women 13.2±1.23; the unipolar patients 11.9±1.2; and the bipolar patients 9.4±1.20. MAO activity did not seem to be related to the euphorogenic (r=.06) or activation effects (r=−.03) of *d*-amphetamine in this sample, in contrast to the findings of a previous report (22).

DISCUSSION

We found significant correlations between the self-rated responses to *d*-amphetamine and the antidepressant effects of imipramine, results consistent with the one previous study reporting a significant association between individual differences in responsiveness to these two drugs (6). We caution that our data and the data of Fawcett and his colleagues (6, 12, 13) do not necessarily imply that *d*-amphetamine response will predict response to imipramine in all patients, because both of these studies used small groups of hospitalized patients who were carefully selected for depressive features. Larger-scale investigations, such as inter-hospital studies, are needed to establish the predictive value of *d*-amphetamine in a wider variety of depressed patient subgroups.

The relationship between the responses to the two compounds disappeared when 8 additional patients were included in the sample after their *d*-amphetamine responses were evaluated. These 8 patients presumably had not responded to a trial of imipramine before coming to NIMH and were currently in the same depressive episode. One possible explanation for the discrepancy between the inpatient imipramine sample and the imipramine nonresponders "by history" may come from the work of Johnson (23) and Kotin and associates (24). These authors reported that depressed patients frequently are inadequately treated with antidepressant drugs before hospitalization, often because of premature discontinuation, incomplete compliance, or inadequate dosage regimens. Since the 8 patients had *d*-amphetamine responses that were similar to those of the NIMH imipramine responders, some nonresponders may have responded to imipramine under strict inpatient supervision and/or with higher doses. Careful clinical documentation before and during

treatment may also have been lacking with these patients. It would seem that quantitative psychological ratings could be useful not only in a clinical-research setting but also as a part of standard clinical practice. Similarly, in our double-blind evaluation of the neuroleptic treatment of schizophrenia, we frequently have found that supposed nonresponders may respond to neuroleptics if the dosage and treatment course are carefully monitored (van Kammen and associates, unpublished data).

Our methodology is somewhat different from that of Fawcett and Siomopoulos (6) in that we used two administrations of 30 mg of *d*-amphetamine on two days that were separated by two days of placebo administration, while they gave two doses of 15 mg of *d*-amphetamine at 7:00 and 10:00 a.m. during the study day. Furthermore, we used only self-rated data (means of three observations) on each of two days. We have previously reported significant correlations between antidepressant responses to *d*-amphetamine found with this self-rating scale compared with observers' behavioral ratings (10).

It is known that *d*-amphetamine acts almost immediately, compared with the longer time required for tricyclic drug effects to appear. The activation, euphoria, and antidepressant responses to *d*-amphetamine are significantly correlated with *d*-amphetamine blood levels (16). It is intriguing that a correlation was found between the two drug responses (amphetamine and imipramine) because much of the variance in response to both compounds has been reported to be accounted for by differences in plasma drug levels among different individuals (16, 25). This raises the question of whether some common factors influencing the blood levels of both drugs (e.g., microsomal enzyme activity, absorption, and distribution) might be present. That a correlation was found between *d*-amphetamine plasma levels and the self-rated response to *d*-amphetamine (16) and between the latter and the observed response to imipramine (this report) may indicate that those patients with only a moderate response to imipramine did not develop sufficiently high blood levels, for example, on the basis of not receiving an adequate therapeutic dose. This possibility suggests the need for clinically available methods for tricyclic blood level determination and for a better understanding of the kinetics of imipramine metabolism.

The amphetamines have been used in the treatment of depression, although their efficacy has not been consistently demonstrated (24–26). However, the individual response is extremely variable (8, 10, 11). In studies with larger groups of patients these individual variations may have accounted for the differences in antidepressant effects of chronic *d*-amphetamine reported by some researchers (27), although not by others (28).

Amphetamines may also have unpleasant side effects—for example, irritability or loss of sleep—which may render more complex the assessment of an antidepressant effect. How sustained the antidepressant properties of *d*-amphetamine are has apparently never been comprehensively evaluated. Since Overall and associates (28) reported the similarity between the antidepressant effects of *d*-amphetamine and those of tranylcypromine (a MAO inhibitor) in depressed patients, apparently no reports of attempts at replication have appeared in the literature. Anecdotal reports indicate that some depressed patients may do well on these drugs, while some psychiatrists use *d*-amphetamine or its congener, methylphenidate, to overcome the lag time in response to tricyclic antidepressants (29).

Low urinary excretion of 3-methoxy-4-hydroxyphenylglycol (MHPG) has been associated with a positive response to imipramine (12, 13, 30–32). Fawcett and associates (12) and Maas and associates (13) have also reported that low treatment urinary MHPG tended to be associated with an antidepressant response to *d*-amphetamine. In a preliminary report on 8 depressed patients receiving *d*-amphetamine (32), low pretreatment MHPG also tended to correlate with an increase in activation response to *d*-amphetamine. MHPG is considered to reflect central norepinephrine metabolism (13). Low pretreatment MHPG excretion is consistent with the norepinephrine hypothesis of depression (33, 34). Schildkraut (30) and Beckmann and Goodwin (31) reported that patients with high pretreatment MHPG excretion values are more likely to respond to amitriptyline. A study similar to ours for amitriptyline may clarify this.

It has been suggested that personality factors contribute to individual differences in *d*-amphetamine response (17, 19). Other factors, such as sleep deprivation, may alter individual responses to *d*-amphetamine (18). In the present study patients who rated themselves as relatively more depressed, anxious, and withdrawn on the MMPI tended to experience less activation in response to *d*-amphetamine. However, in apparent contrast to the report of Kiloh and associates (17), depressed patients in the present study who had higher MMPI hysteria scale scores reported feeling relatively less dysphoric during the amphetamine trial. It may be assumed that the relationships between the amphetamine response and the personality factors are largely chance findings.

A worsening of depression in the morning has been considered a sign of endogenous ("vital," serious) depression in contrast to neurotic depression, which may be worse in the evening (35, 36). Endogenous depression responds better to tricyclic antidepressants than does neurotic depression. Our data do not indicate that a diurnal variation in depressive symptoms correlated with *d*-amphetamine responses.

Third-Party Payers: To Pay or Not to Pay

BY STEVEN S. SHARFSTEIN, M.D.

Insurance companies have traditionally been wary of providing coverage for mental illness for two reasons: 1) they fear that people would bring a mental illness on themselves or would use treatment for self-actualization, and 2) they fear the risk of providing never-ending treatment for "incurable" illness. The author states that the insurers' fears are groundless but suggests that psychiatrists research the utilization and costs of their treatments in insurance plans collaboratively with the actuaries who determine policy and premiums. Retrospective and prospective criteria for outcome and effectiveness of psychiatric treatment must be developed and applied.

THE EXTENT to which health insurance meets the cost of psychiatric services is limited. In their landmark publication *Health Insurance and Psychiatric Care: Utilization and Cost*, Reed and associates (1) estimated that only 12.5% of expenditures for mental health care in 1968 was paid for by health insurance. Although there is some reason to believe that this particular figure is expanding, it is still estimated to be far below the coverage by insurance benefits for physical illness, which represents over 25% of total personal health care costs. The historical reasons for less coverage for mental health care under health insurance are complex, and major issues today remain cloudy. It is the purpose of this paper to review the difficulties insurance carriers have in "working through" insurance coverage for psychiatric care.

In the early development of health insurance in the United States in the late 1930s there was debate over which services should or should not be covered and the extent of such coverage. One overt concern then and perhaps a more covert concern today regarding mental health coverage was something called the "moral hazard" of the insured. This is defined as any characteristic of an insured person that tends to increase the likelihood and/or the severity of a situation for which the person has insurance. Insurance presupposes that the covered situation is likely to be a chance event uncontrollable by the insured person. If the insured person finds it desirable to develop the condition for which he or she has the insurance, it undermines the whole integrity of the insurance system. A dramatic example of this is setting fire to one's own house in order to collect homeowner's insurance.

Mental illness and substance abuse in our culture are not seen or understood in the same way physical illness is understood. The mentally ill individual is considered more responsible for bringing on himself or herself an anxiety state, depression, or an alcohol problem. Furthermore, there is the cultural stereotype that relatively healthy people seek psychoanalysis for self-actualization or self-fulfillment rather than because they have developed an incapacitating illness that requires treatment. In the 1950s the case for coverage of mental disorders under insurance was set back by the experience of the Actors' Equity: many of the enrolled population promptly went into psychoanalysis after insurance that covered this treatment was provided to them. Today, in the Federal Employees Health Benefits Program, which maintains excellent coverage for nervous and mental disorders, the discussion rages in relation to longer-term treatments as to whether the care is medically necessary and appropriate. More and more confidential information is being required by insurance carriers to ascertain the medical necessity of continued treatment; special concern is voiced about psychoanalysis.

THE ROLE OF THE PUBLIC SECTOR

Mental health services contrast with other health services not only in the fact that they represent a lower proportion of the cost paid by health insurance but also in the fact that a dramatically higher proportion of the costs are paid by the public sector—chiefly state and local governments. Two-thirds of all mental care costs come from this sector, compared with less than one-third for all other health care. The public institution and the traditional custodial care provided in public institutions have fixed an ugly image of mental health care and treatment in the public eye. Despite recent developments many people feel that serious mental illness is incurable and drains public and private resources of society. The issue of public support

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Sharfstein is Director, Division of Mental Health Service Programs, National Institute of Mental Health, Alcohol, Drug Abuse, and Mental Health Administration, 5600 Fishers Lane, Rockville, Md. 20852.

The views expressed in this paper are the author's and do not represent the official views of the National Institute of Mental Health, Alcohol, Drug Abuse, and Mental Health Administration.

for the lion's share of mental treatment is also related to the fact that different types of mental illness are related to social class. Studies associating the most severe pathologies with the lower social classes maintain the poorhouse image for treatment of the mentally ill.

Thus at the one extreme private insurance companies are wary of mental coverage because of the "moral hazard" of people bringing a mental illness on themselves or seeking self-actualization or self-fulfillment through mental treatment, and at the other extreme they are wary of the thousands of "incurables" who languish in custodial institutions. The insurers fear that either extreme will bring financial ruin to an insurance program.

EXPLODING THE MYTHS

Since the 1950s dramatic developments have brought mental health care into the mainstream of general medical care. These changes include the development of psychiatric units in general hospitals, the effective use of psychotropic medications, and the shift in locus of care away from the remote long-term custodial institutions back to the community. Data from recent studies of health insurance plans and the community mental health centers program indicate that the fears of insurance companies about the utilization and costs of mental treatments are groundless. Data from the Blue Cross/Blue Shield federal employee plan, for example, with its very generous coverage for psychiatric conditions (with cost sharing), indicate that the proportion of mental and nervous to total health benefits has stabilized at around 7.5% for the past 5 years (2). Data from the provincial program of medical care insurance in Canada indicate that the proportion of psychiatric care to total medical payments is between 1.4% and 5.4% in various provinces, depending on the availability of psychiatrists (2).

Furthermore, data from community mental health centers indicate that long-term care is much more the exception than the rule. The 1973 data from community mental health centers in Kentucky show that 87% of outpatients were seen for 10 or fewer visits per episode of care (3). Even in state and county mental hospitals, most inpatient care is now for less than 30 days; these hospitals thus meet the definition of acute short-stay hospitals (3).

The compelling accumulation of utilization and cost information is forcing both private health insurance companies and national health insurance planners to reassess the role of mental health coverage. Major medical insurance coverage almost always includes a short-term psychiatric hospitalization benefit (30–45 days/year) and limited short-term outpatient visits (10–30 visits/year). An issue of concern, however, is the extent to which mental care can be reviewed in a similar fashion to physical care, especially in the outpatient sector. The insurance industry must provide more evidence of the "cost legitimacy" of the benefits it pays. The rapid escalation in health care costs endangers the accessibility to all health care. Therefore, third-party payers insist that the provider of care demonstrate that every dollar spent is for medically necessary and appropriate care.

ACCOUNTABILITY OF MENTAL HEALTH COVERAGE

Most inpatient psychiatric care can be reviewed on the basis of admission criteria and by length-of-stay norms. It is in the outpatient sector that the review of psychiatric care becomes more problematical. This is especially true in the case of intensive outpatient psychotherapy and psychoanalysis. The following issues are often raised:

1. What is the validity of the diagnosable condition? Is it a medical condition? The fact that most outpatients superficially seem to function well in work and with their family is inconsistent with the medical model, which assumes incapacitation from disease and assumption of the patient role.
2. Is the treatment offered the most cost effective? Would shorter term individual treatment or group treatments produce an equally good result?
3. What are the qualifications of the person who provides the treatment? Since there is no Board certification for intensive psychotherapy, who is qualified to conduct this technically demanding treatment? Why is a medical degree necessary for talking treatments? Which nonphysicians are qualified?
4. To what degree does the communication of information from the person who provides the treatment to the insurance carrier compromise the privacy of the therapist-patient relationship? Most mental health professionals insist on a need for strict confidentiality in order for psychotherapy to proceed. If there are many questions about the medical necessity of treatment, its length and intensity, and the qualifications of the provider, how much and how often must such information be provided to an insurance company or other third-party payer? How much peer review should be expected for this treatment? What about prior authorization? When does providing the information interfere with the treatment itself?
5. Finally, in any open-ended benefit structure, the question remains at what point you can say that treatment has gone far enough and should go no farther.

Quality assurance efforts and the review of the necessity of continued treatment presuppose a model that may be antithetical to psychotherapy. The law of diminishing marginal return applies to most medical conditions: this is to say that in any given medical treatment a (usually predictable) point is reached where an additional increment of the medical treatment will not provide an additional increment of health. With psychotherapy, however, it is unlikely that a predictable increment of health will be evident with each increment of treatment. The phenomena of

resistance, regression, and negative transference lead to a wave curve of treatment progress. An increment of treatment could lead to a decrement of mental health over the short term; only much later will the progress toward health resume. How, then, is one to measure progress in the course of a treatment that defies the law of diminishing marginal returns? Also, how can the insurance companies and other third parties be educated about the differences in psychiatric treatments without completely throwing out the medical model?

We have little experience in the review of psychiatric care. Only recently have we been able to demonstrate the cost stability and predictability of comprehensive mental coverage under health insurance, and this is not enough. Research on the cost-effectiveness issue that is related to health outcomes and is convincing is necessary. A model for such research was provided in West Germany 20 years ago.

WEST GERMAN INSURANCE STUDIES

Duehrssen (4, 5) and her colleagues at the Central Institute of Psychogenic Illness of the Berlin General Health Insurance Office did an extensive follow-up of patients who had had analytic psychotherapy or psychoanalysis. They developed a system for evaluating patients at the onset of treatment and at the end of treatment and then followed up on nearly 1,000 patients after 5 years. The criteria used for evaluating patients in this study included 1) a precise description of the symptoms of illness as well as its duration, 2) data on utilization of general health care, especially in-hospital care, 3) data on the work capacity of the individuals, and 4) self-evaluations of the treatment by the patients themselves.

The 1,004 study patients who underwent individual analytic psychotherapy or psychoanalysis had had an average number of 100 hours of treatment. Twelve percent ended treatment prematurely, 12% continued privately after their insured limit of 200 visits ran out, and 10% said they wanted further treatment after 200 visits but could not afford further treatment. The researchers could not find 101 of the study patients at 5-year follow-up, 13 had died, and 845 of the remaining 890 patients were evaluated, providing an extremely high response rate. Only 45 of the 890 patients refused to provide follow-up information. In 5 years 647 patients were followed up by direct interviews, 104 returned detailed questionnaires, and 94 had home visits by a social worker.

In terms of outcome, 13% of the patients were judged to have had at least one relapse during the 5-year follow-up period. The most interesting statistic was that of 845 patients, the hospital rate was .78 hospital days per year, which compared with a pre-treatment average of 5.3 days per year and a general average for the insured population of 2.5 hospital days per year. This included hospital days for any illness, not just mental illness. Prognostic measures built in at the onset of treatment also had a high degree of validity and reliability: patients wtih favorable prognoses had excellent outcome measures at the termination of treatment and this held true at 5-year follow-up. There was also a very high degree of patient satisfaction: 81% felt strongly at 5-year follow-up that they had been helped by the treatment.

Although there were some methodological problems with this study, it is clear that follow-up had been conducted on a large number of patients with a sufficiently long interval between treatment and follow-up. This kind of research helped both preserve and extend the national health insurance benefit for the mentally ill in West Germany and led to a more efficient and effective prior authorization and peer review system throughout that country.

WHAT CAN PSYCHIATRY DO?

Psychiatry is a part of medicine. Together with other physicians, psychiatrists must promote the value of their treatments to the public and must be accountable for the costs. Continued study of utilization and costs in both private and public insurance plans is necessary and should be done collaboratively with the actuaries who determine policy and premiums. Working with insurance carriers also means mutual education: psychiatrists could decide on the rationale for particular treatments, especially as they depart from the "medical model." Standards for claims reviewers must be developed so that there is a system of accountability that allows for increasing intensity of review based on flagging criteria and leading to timely peer review. These standards must include adequate safeguards for confidentiality.

Peer review must be more than a ratification of the "usual and customary." It must begin to develop a body of knowledge similar to case law and then be able to apply this knowledge around the country. Outcome and effectiveness criteria must be developed and applied—not only retrospectively but prospectively, as it was in the West German studies. Both the insurance industry and psychotherapists have an interest in demonstrating cost savings as a result of psychiatric treatments. It is astonishing that so little has been done to demonstrate such savings in the United States to date (6–8). What has been done is tantalizing but not so overwhelmingly persuasive as to overcome long-held beliefs on the uninsurability of mental illness. As a result, generous national health insurance coverage for psychiatric disorders in in doubt. As treatments depart from the perspective of the medical model it is essential to make extra efforts to justify their necessity and cost effectiveness. If the evidence on cost effectiveness is unconvincing, national health insurance in the United States will not pay for treatment for mental illness. This kind of care is costly. Who will pay?

Foundations' Fund Prize for Research in Psychiatry

The American Psychiatric Association is inviting submissions for the second annual Foundations' Fund Prize for Research in Psychiatry.

Candidates for the prize should be citizens of the United States or Canada and should be nominated by a sponsor. Sponsors should be members of the American Psychiatric Association. Members of the prize board are excluded from submitting nominations.

The *sponsor* should submit a supporting letter justifying the nomination in detail and summarizing the nominee's research accomplishments.

The *nominee* should submit the following:

1) An up-to-date curriculum vitae,
2) An up-to-date bibliography,
3) A group of representative and thematically linked papers or books published (or accepted for publication) in English and dated within 10 years of the deadline for submission, and
4) A summary statement written by the nominee that emphasizes the principal theme or themes running through the work and its internal cohesiveness and consistency.

Six copies of each entry should be submitted to Joel J. Elkes, M.D., Chairperson, Foundations' Fund Prize Board for Research in Psychiatry, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Entries will be acknowledged but cannot be returned. The award will be presented at the Convocation of Fellows at the APA annual meeting in May 1979.

The deadline for submission is December 1, 1978. Any entry received after that date will automatically be entered for consideration for the 1980 award unless withdrawn by the nominator or candidate.

Combat Neurosis in Inner-City Schools

BY ALFRED M. BLOCH, M.D.

The author studied 253 classroom teachers who were referred for psychiatric evaluation because of varying degrees of psychological stress and physical trauma. These teachers had experienced actual assault or the threat of assault in inner-city schools. The author evaluated these patients' ego functioning, attitudes, current life situations, and the presence of any predisposing factors. On the basis of these evaluations and using guidelines established in studies of combat neurosis, he recommends that individuals who experience severe occupational stress be provided psychological training to prepare them to handle stress, constant support of and access to people in administrative positions, and a mechanism for crisis intervention.

THE CONCEPTUAL FRAMEWORK provided by definitive studies of military casualties more than 30 years ago by Grinker and Spiegel (1) and more recently by Glass (2) and others (3–6) established clearly the causal relationship between continued environmental stress and strain and symptoms of psychological and psychophysiological manifestations of traumatic war neurosis, or "combat neurosis." I have observed a more recent form of combat neurosis. Classroom teachers in inner-city schools are seeking treatment for symptoms of continual psychological stress and physical assaults that result in temporary and sometimes total decompensation. A group of these "battered" teachers form the data base of this study. These people face environmental stresses that have been and still are escalating.

Since 1972, classroom murders have increased 18%, rapes 40%, robberies 37%, and physical assaults on teachers 77% (7). According to *Newsweek* (8), the Senate Subcommittee on Juvenile Delinquency reported that during the academic year 1975 vandalism and violence in schools continued to increase: annual destruction of school properties exceeded $600 million, and 70,000 classroom teachers reported serious injuries from physical assaults by students. Many more injuries are probably never reported. For a variety of political reasons, the quantitative and qualitative extent of such physical assaults is not widely acknowledged.

Unless powerful defense mechanisms are used, the response to danger is fear, the most potent source of arousal of the autonomic nervous system. Changes are effected in respiration, blood pressure, and catecholamine secretions (increased plasma corticosteroid concentrations and urinary steroid excretions). Sustained arousal of hypothalamic action systems channeled to differenct target organs has been shown to culminate in such diseases as hypertension, peptic ulcer, and diabetes mellitus (9–11). Many of the psychological symptoms evident in the teachers who seek treatment are also analogous to those observed in combat neurosis: emotional tension (anxiety, insecurity, nightmares, excessive startle response, phobias), cognitive impairment, and conversion symptoms.

Although there are many studies of various causative aspects of juvenile aggression leading to violence in schools, these only illustrate Holt's concept that "the school is the battleground of society" (12). I am aware of no comprehensive study of the effects of violence and its psychological and psychophysiological sequelae in classroom teachers who have been its target. These people are on one of the front lines of society. Others on the front lines include the police, but they have chosen to be there, they are better equipped physically and psychologically for such duty, and they possess devices for self-protection and implementation of their will.

PATIENTS

The patients selected for this study were 253 classroom teachers (158 women and 95 men) from Los Angeles inner-city schools. All of these teachers were victims of varying degrees of psychological stress and physical trauma. Evaluated during the period of October 1971 through June 1976, these patients were white, black, Mexican-American, and Oriental and had taught in inner-city schools for periods ranging from 3 months to 14 years. Their average age was 42, with a range of 23–61. They were referred to me for psychiatric evaluation by a variety of sources, including other physicians, coworkers, union representatives, and attorneys representing them in Workers' Compensation applications.

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

The evaluations of these patients revealed an evolving pattern dramatically similar to that seen in early studies of combat neurosis, with implications for diagnosis, treatment, and, more importantly, prevention. The teachers themselves referred to the schools they worked in as the combat zone. Therefore, I used studies of combat neurosis (1–6) as guidelines in assessing the results of the psychiatric evaluations of these patients and in testing the patients.

Before each psychiatric evaluation I reviewed each patient's medical record. I then evaluated the patient's ego functioning, attitudes, current life situation, and the presence of any predisposing factors. Each patient routinely completed a Minnesota Multiphasic Personality Inventory (MMPI), the Bender Gestalt Perceptual Motor Test, and the Beck Inventory of Depression. If there was an indication of organicity or psychosis, projective testing was also performed. Testing was also used as an indicator of progress in treatment.

SIGNS AND SYMPTOMS

Review of Medical Records

Because these teachers' employment contract provided medical coverage (usually with the Kaiser Permanente Medical Group), a clear, well-documented chronological medical record was sent to me before my evaluation of the patient. Therefore, unlike in the earlier studies of combat neurosis, I had documentation of the fact that 134 of the 253 teachers had extensive medical histories representing 2–10 years of psychophysiological response to continued stress. These data also allowed a more comprehensive study of symptoms developed during their teaching career due to the stress response of repeated and sustained arousal of hypothalamic action systems channeled to different organs, with resulting cardiovascular, gastrointestinal, and respiratory disorders. Important life stress events and the development of symptoms for which medical consultation was sought could usually be correlated.

Clinical Evaluation

Twenty-eight percent of the patients had sustained actual physical assault on campus. They had suffered lacerations, bruises, head injuries, seizures, and deafness. Most of the physical injuries were minor, however. Those who had been attacked without provocation or did not know their assailants seemed to experience the greatest difficulties. The majority of assaults were of this type.

The symptoms described by Grinker and Spiegel (1) of hypochondriasis and conversion phenomena were evident in these patients as complaints of fatigue, weakness, blurred vision, tinnitus, irritability, sensitivity to weather, dizziness, malaise, and a variety of depressive equivalents. Almost all of the patients had some psychophysiological manifestations of long-term stress. I frequently observed during the interview that mental reliving of stressful events reproduced the psychophysiological responses. Other similarities to patients with combat neurosis included predisposing personality factors, the patients' tendency to focus on somatic symptoms, and their impaired morale and sense of futility. A relatively minor physical injury or somatic complaint often became the unconscious focus of psychological decompensation with ego-syntonic secondary gain. Depending on the particular target organ, the symptoms of these patients represented the entire spectrum of stress-related illness (see table 1).

Psychological testing generally indicated obsessional, passive, idealistic, dedicated individuals who were unable to cope with or understand the violence directed toward them. They were unable to defend themselves or strike back. Unconsciously, these patients identified authority figures as parental figures with idealized attributes of wisdom, justice, love, and protection. The patients' levels of anxiety and depression were consistently high, and they had a tendency to focus on various somatic expressions of anxiety.

Predisposing Factors

Factors predisposing to neurosis in military personnel were applicable to these teachers (13–15). Primarily, these centered around an impaired ability to deal effectively with fear or anger. Almost 80% of the teachers who succumbed to sustained stress were categorized as passive, rigid, and moderately obsessional. They were moralistic and had relatively harsh super-egos. Unable to strike back when they were the target of violence or hostility, they internalized their fear and rage.

It is important to emphasize that none of the patients in this study had received any psychological or physical training to prepare them to face the threat of violence in the schools. Without this basic training they were unable to facilitate optimal autonomic function during crisis or attack (16–18).

Environmental Stress

The continuum of violence directed toward these teachers included repeated threats of murder and/or rape. Actual physical assault and injury occurred, as did theft, arson, and vandalism of their property. Threats of a brutal attack were often more psychologically disabling than the actual event. Campus violence not specifically directed at these teachers included bombing of school buildings, theft and destruction of campus equipment, fights between students and gang members, murder, rape, and the presence of weapons on campus. Student locker searches revealed drugs, dynamite, knives, ammunition, and firearms. The presence of anonymous gang members and campus vagrants in inner-city schools is a major source of violence and has caused continued anxiety to the students and faculty.

TABLE 1
Primary Physical Complaints of 253 Teachers Referred for Psychiatric Evaluation*

Complaint	Number of Patients
Gastrointestinal disorders: burning, cramping, nausea, diarrhea, ulcer, colitis, other	114
Musculoskeletal disorders: functional overlay to injury, backaches, other	34
Respiratory disorders: asthma, frequent bronchial infections, other	31
Headaches: migraine, tension, other	29
Cardiovascular disorders: palpitations, hypertension, coronary artery disease, atherosclerosis, other	19
Skin disorders: neurodermatitis, allergies, other	14
Miscellaneous: hypochondriasis, conversion symptoms, other	12

*Almost all of the patients had symptoms representing more than one system involved in the stress response. Headaches and gastrointestinal symptoms were extremely common.

Many of the patients reported that their classrooms were overcrowded by as much as 75%. These classes often contained a large proportion of violence-prone continuation students, many of whom had police records of juvenile delinquency and detention. The teachers reported that when violence-prone or acting-out students became disruptive in class they were sent to the administrator's office. They usually returned promptly without having been reprimanded. If they assaulted a member of the faculty, they were suspended from school for a few days and then returned, often as heroes to their classmates.

Sixty-eight percent of the patients reported that they had been discouraged from discussing the incident with other members of the faculty. Thus, they were denied an important opportunity for obtaining support and reality testing. The majority of the petitions submitted annually by teachers requesting transfer to less stressful schools were denied. The added stress of no exit from what they viewed as an intolerable situation contributed to the development of symptoms. Psychophysiological complaints increased until many became disabled.

Morale and Leadership

The teachers felt especially demoralized when, in attempting to report an attack, they found the principal to be indifferent or, worse, fault-finding. Many, like rape victims, were made to feel responsible for being assaulted.

After sustaining a prolonged battering from an angry black student wielding a chair as a weapon, a white teacher reported the assault to his principal and was informed, "This [incident] is your fault and reflects your inability to communicate with the minorities." The patient has not returned to teaching. The same teacher had survived an even greater physical assault a year earlier. In that instance, however, he had felt the immediate and complete support of a different administrator. He had returned to his classroom the next day. When asked to subjectively correlate the effect of the lack of administrative support in the more recent incident to his inability to resume his teaching career, this patient unequivocally acknowledged that he would still be in the classroom today if the situation had been handled better. This experience of crossfire is not unique and contributes substantially to disability and the need for psychiatric treatment among battered teachers.

The teachers said that they were usually discouraged from reporting incidents of violence. Although legally required to do so, they received the implicit (and sometimes explicit) message that it was "not in their best interest" to pursue the matter, i.e., that the administrators might consider them unsuccessful. They thus functioned under a two-edged Damoclean sword: the threat to their job security and the ordeal of facing continued classroom and campus violence.

CONCLUSIONS

These teachers had symptoms of posttraumatic or combat neurosis as clinically defined. The relationship of stress to physiological response and physical illness has been well documented in certain diseases. The relationship between stress and psychological depletion has also been studied extensively. Although the psychiatric needs of teachers who succumb to stress still require further definition, I reviewed the effects of trauma and stress on these patients by applying the guidelines used in studying the survivors of war. The consensus of military studies of morbidity following periods of stress was based primarily on the following factors: 1) severity of the event, 2) chronicity of the stimulus, 3) unexpectedness of the event, 4) lack of counterbalance to unpleasant stimuli, and 5) impaired morale. The patients reported on here have shown the same correlation between incidence of symptomatology and factors of stress as was shown in the military studies.

RECOMMENDATIONS

Careful investigation of etiological factors in the problems of these patients indicates that certain prophylactic measures can be taken to diminish or avoid the psychological and psychophysiological breakdowns observed. With appropriate modification, these measures may be applicable to other individuals who experience severe occupational stress (e.g., firemen, policemen, and social workers).

Preparedness

Psychological training to prepare people for stressful situations must take place to minimize the impact of violence. This training could include rehearsing and familiarizing the teacher with potential violent events.

This would develop a qualified rather than a total belief in personal vulnerability and would teach methods to cope with and diminish the anger of violence-prone, acting-out students. The teacher could be taught to understand the language of the streets as well as the games students play. Skillfully handled, one of these provocative games can result in a shared joke that improves morale. Poorly handled, the game can have catastrophic results.

Morale

As in war, morale is a critical factor for teachers who deal with violence. The opporuntity to share his or her experience with another person or with a group and to work through some of the problems should always be available. This would represent an acceptance of the events and consequences of campus situations, reduce the psychic load on the battered teacher, and facilitate individual development, improving morale through constructive attitudes and efforts. "Rap groups" led by teachers with mental health experience could be useful in this situation. If assault or breakdowns occur, leaders with greater expertise must be used.

The teaching staff, especially in schools with high profiles of violence, must be able to believe in the absolute and constant integrity and support of the school and district administrators. The teacher must feel the support of the school administration. Teachers assigned to schools with high profiles of violence should be rotated to less stressful schools after a specified period (perhaps 2 or 3 years).

Students who have attacked a teacher or staff member should not be allowed to return to the same school. Too often, these students return as heroes to the other students after 1 or 2 days of suspension. They siphon the energy of the teachers and obstruct the learning opportunity for the majority of students.

Classroom teachers should have an opportunity to report directly to the school board concerning such issues as adverse school conditions, unfair administrators, overcrowding, and violence. This is most important; it enables the individual to sustain the hope that someone will be made aware, that some change for the better may occur, that there has been some meaning or value to their suffering. They should be encouraged to report incidents of acute or chronic stress rather than discouraged.

Crisis Intervention

A crisis intervention team should be assigned to each school district. This team would consist of two teachers with mental health training who would be supervised by a psychiatrist or a clinical psychologist. Their function would be to defuse crises by implementing open-forum discussions at schools where teachers and students are involved in conflict. The crisis team would offer the immediate and subsequent psychiatric care needed to decathect trauma if a teacher's stress response syndrome is not worked through and mastered. A teacher-oriented walk-in clinic should be available. To be effective, there must be no conflict of interests in the orientation of such a setting.

The problems described in this paper are increasing rather than decreasing. Every effort must be made to minimize the violence or stress itself as well as the impact of that stress on students and teachers. I hope this study and its recommendations represent a step in that direction.

Patient-Therapist Matching: A Research Evaluation

BY JOHN G. GUNDERSON, M.D.

The author tested the predictive power of 10 hypotheses about the personality qualities of therapists that match with those of schizophrenic inpatients to affect therapeutic course. The personality matching traits predicted with significant accuracy the quality of the therapeutic relationship and even the type of overall clinical outcome. Examination of the data revealed that most of this surprising predictive strength derived from a group of highly intercorrelated personality qualities. Taken together, these qualities reflected a capacity of therapists to be comfortable while being involved with a variety of strong affects in their schizophrenic inpatients. The limitations of this study and its advantages over the A-B typology are discussed.

THIS PAPER describes a research effort to evaluate the validity of 10 hypotheses about personality dimensions of psychotherapists that match well with particular personality characteristics of hospitalized patients, primarily schizophrenics. The hypotheses about patient-therapist matching arose from discussions in a Washington, D.C., psychotherapy of schizophrenia study group.[1] This study derives from the clinical observation that the qualities of psychotherapists who work well with schizophrenic patients are impossible to define without relating such qualities to corresponding characteristics of the patient with whom the therapist is to work. The clinical and theoretical background of this study has been described elsewhere (1, 2).

The best-known effort to distinguish characteristics of good (type A) and bad (type B) therapists with schizophrenics is the Whitehorn and Betz study (3). That study and the many which followed it (4) have attempted to correlate the effectiveness of treatment with the therapist's score on the Strong Vocational Preference Blank. Despite the great amount of work that has been done, the significance and meaning of the A-B typology have remained elusive. The hypotheses tested in the present study differ by focusing directly on clinically meaningful personality dimensions of patients and therapists. The focus on personality dimensions arises from the belief that it is especially valuable to match the therapist's personality with schizophrenic and other very disturbed patients because of the relative importance of the "real" relationship during the critical initial phases of therapy (5). This impression has been confirmed by the Menninger psychotherapy study (6) and, more specifically with schizophrenics, by Rogers and associates (7). The personality dimensions are intended to be qualities that might exist relatively independent of the therapeutic situation.

In clinical practice the subcategorization of schizophrenia is more likely to be done according to personality characteristics than symptoms; that is, patients are more frequently described as suspicious, hostile, or seductive rather than catatonic, hebephrenic, or even as having a chronic versus an acute breakdown. Just as with therapists, the personality characteristics of the patient that are enduring and somewhat independent of the specific symptoms manifest during acute regressions are felt to be especially important in attempting to match the patient with the therapist. Table 1 indicates 10 qualities of patients and the corresponding qualities of therapists that were hypothesized as making for either a good or bad match.

RESEARCH DESIGN

The 10 hypotheses about matching listed in table 1 were translated onto separate rating forms for patients and for therapists (1). On these forms each of the 10 personality dimensions for a sample of patients and their therapists was rated on a 1-to-5 anchored scale. From these ratings a prediction about the quality of the match could be made when the profiles of the patients and therapists revealed evidence of either a mismatch or a particularly good match. In about one-third of the matches no suggestion of either good or poor matching was apparent and no prediction could be made. For matches where predictions were made, these were

TABLE 1
Ten Hypotheses About Matching Personality Qualities of Patients and Therapists

Patient Quality	Type of Match	Therapist Quality
Passivity: submissive, passive, compliant	Good	Activity: energetic, playful, intrusive
	Bad	Passivity: "analytic," unstructuring, impassive
Hostility: irritable, belligerent, assaultive	Good	Comfort with aggression: either as a "Grandma Moses" or a "Napoleon"
	Bad	Lack of this quality: anxious, "chicken"
Paranoia	Good	Externalization: blames, antiauthoritarian, sympathizes with victims
	Bad	Naiveté: ready trust
Sociopathy: addictive, impulsive, manipulative	Good	Political: adventurous, flexible, power conscious
	Bad	Prudishness: conventional, rigid, principled
Fragility (of defenses): sensitive, regression prone, excitable	Good	Gentleness: easygoing, soft-spoken
	Bad	Intense: assertive, loud, boisterous
Seductiveness (involvement with sexual id, body matters)	Good	Grandfatherliness: accepts id material without excitement or judgment
	Bad	Lack of this quality: puritanical or seductive
Depression: sad, helpless, suicidal	Good	Comfort with depression: patient knows grief "inside out"
	Bad	Lack of this quality: responds with sympathy, anger
Hopelessness (prognostic): chronic, incurable	Good	Optimism: charismatic, tenacious, grandiose
	Bad	Pessimism: scientific, selective, realistic
Anxiety	Good	Composure: contained, reasonable, stable
	Bad	Frenzied: frenetic, disorganized
Dependency	Good	Comfort with dependency: independent, has mastered separation
	Bad	Lack of this quality: lonely, needy, guilty

correlated with the patients' subsequent clinical course.

To help isolate the matching variable from the many factors that influence clinical course, this study used a sample of patients who changed therapists during their treatment. This design became feasible because of a data base provided by a survey of the psychotherapy experience at McLean Hospital in the 1960s.[2] From the over 500 psychotherapy cases that were surveyed, there was a subsample of 50 patients who had 2 or occasionally 3 therapists during the course of their hospitalization. About 85% of the patients in this sample had been diagnosed as schizophrenic. The usual reason for a change of therapist was because problems had arisen in the psychotherapy work with the first therapist. Occasionally there were changes because the first therapist had become unavailable. As part of the hospital survey, when therapists finished working with a patient they were asked to evaluate two factors: the clinical outcome and the quality of the therapeutic relationship.

Ratings on the therapists' dimensions were done independently by two experienced clinicians (Drs. Stanley Eldred and Arthur Cain) who knew all of the therapists involved. Ratings on each patient's personality dimensions were made retrospectively by the therapist who had worked with the patient. The numerical scores provided by the ratings of patients and therapists formed the basis for research predictions as to the quality of the patient-therapist match. These predictions were made without any knowledge of the identity of the patients or the therapists, the sequence in which the two or three therapists worked with a given patient, or the frequency of outcome type (in terms of success or failure).

[2]This work, titled "Psychotherapy at McLean," was prepared by Dr. A. Cain in 1973 and is available from him at McLean Hospital.

RESULTS

Interrater Reliability

Previous reports on the patient and therapist scales have indicated that clinically experienced raters can achieve reasonable reliabilities (1). In the present study the two trained raters evaluated all therapists independently, and their mean score was used for the actual study. The interrater reliability of ratings in this study was .6 (intraclass correlation coefficient).

Predicting Matching Success

The first hypothesis to be tested was that the scores would accurately predict that a particular patient-therapist match would correlate with the clinical outcome. Data were available on 49 matches; the predictions were correct for 31 of them ($p=.044$, binomial test). Because other treatment and situational factors certainly contributed to the overall outcome, the predictions were then compared with the therapists' judg-

TABLE 2
Accuracy of Predictions and Therapist Ratings of Clinical Outcome and Therapeutic Relationships

Therapist Rating	Predictions		p*
	Accurate	Inaccurate	
Clinical Outcome			
Good	25	4	.00007
Poor	6	14	.979
Total	31	18	.044
Therapeutic Relationships			
Excellent	8	2	.055
Good	13	2	.004
Fair	4	0	.0668
Poor	1	4	.969
Total	26	8	.0018

*Binomial test.

ment about the overall quality of the therapeutic relationship. This correlation was felt to test a narrower goal that is more specific to patient-therapist matching. Judgments about the quality of the relationship were available for 34 matches; the predictions agreed with the therapists' judgment of the quality of the relationship in 26 cases (p=.002, binomial test). This shows that the scales were better able to predict the quality of the therapeutic relationship than the overall clinical outcome. The predictions tended to be more accurate when the clinical outcome or the relationship went well than when it went poorly (see table 2). Thus the scales seemed better designed to indicate good matches than to detect poor ones.

Predicting the Effect of Changing Therapists

The second hypothesis to be tested was whether an accurate research prediction could be made on the effect of a switch from one therapist to another. The 2–3 therapists were rank ordered in terms of their likelihood of success with a particular patient without foreknowledge of the actual sequence of the therapists. This allowed an unbiased prediction to be made on the effect of the switch after the sequence of the therapists was made known. Of the 14 cases for which information was available, 11 predictions were correct (p=.031, binomial test).

The Predictive Power of Each Hypothesis

Two methods were used to determine what predictive weight should be given to each of the 10 matching dimensions. In the first method records were made of whether and with what frequency each dimension correlated positively or negatively with the clinical outcome (see table 3). The most accurate predictor was the dimension of the therapist's composure in the presence of the patient's anxiety. This was also the most frequently used predictor. Other dimensions that emerged as having strong predictive power—when there was either good or poor matching on them—were the therapist's grandfatherliness with seductive patients and the therapist's comfort with aggression for hostile, physically threatening patients. That the comfort with depression and the grandfatherliness dimensions both emerged among the better predictive items confirmed the earlier clinical judgments and research impressions obtained from listening to case conferences (1). The dimensions of sociopathy and, especially, of optimism seemed to be poor predictive items. The dimensions of externalizing, gentleness, and comfort with dependency showed very little predictive strength.

The second method of determining predictive weight was by a multiple regression analysis. This analysis confirmed that the variable which accounted for most variance in outcome was the same one, "composure," that predicted outcome best using the first method. The second, third, and fourth variables (optimism, gentleness, and externalization) were all negative and were among the weakest predictors above. This means that reversing the direction of these hypotheses would allow them to add to the predictive power of composure. The fifth component of the regression analysis (comfort with depression) was positive but added very little.

Intercorrelations of the Therapist's Personality Dimensions

There was considerable interdependence of ratings of some dimensions upon each other. Most striking was the high intercorrelation between the dimensions that were strong predictors; for example, composure correlated highly with comfort with aggression (r=.82), comfort with depression (r=.70), and with grandfatherliness (r=.52). The fact that the strong predictors had generally higher overall mean intercorrelations with all other dimensions suggests that they gain their power by being more global or encompassing (see table 2). This was particularly evident with the "comfort with" dimensions (composure, grandfatherliness, comfort with aggression, depression, and dependency). This analysis then supports the conclusion that the "comfort with" dimensions all reflect a global factor in the therapist, and its predictive strength is largely captured in the one therapist dimension of composure.

Despite the generally high intercorrelations, there were some dimensions that maintained considerable independence, e.g., optimism, sociopathy, activity, and gentleness. None of these was a good positive predictor. It is likely that the predictive strength of these dimensions was weakened by their specificity.

Influence of Overall Similarities

It is possible that individual hypotheses are not so important as the overall similarities between the profiles of the therapist and of the patient on the 10 dimensions. To test this, the scores of the differences between the patient and therapist were totaled and then correlated with the clinical outcome. Those 19 matches with the largest differences were no more likely to have a poor outcome (9 matches) than a good outcome (10 matches). Similarly, the 31 matches with the great-

TABLE 3
Predictive Weight of Each Dimension

Dimension	Number of Times Used	Ratio Right:Wrong	p*	Rank Order	Mean Correlation with All Other Dimensions
Activity	13	8:5	.2905	5	.143

Optimism	10	3:7	.9453	10	.094
Composure	37	26:11	.0107	1	.250
Comfort with dependency	29	16:13	.3717	6	.234

*Binomial test.

er similarity failed to predict good outcome (17 matches) more frequently than poor outcome (14 matches). If overall similarities or differences in the profiles were important predictors, then a patient having 2 therapists could be expected to work better with that therapist whose profile was more similar to his or her own. This hypothesis was also tested and was not found to be valid. These results suggest that the predictive power of the research instruments derived from the specific clinical hypotheses and not from overall profile similarities or differences as recorded by the scales.

DISCUSSION

The results reported here support the idea that certain personality dimensions in the therapist are important predictors of how well he or she can work with certain schizophrenic patients. The matching dimensions that proved to be the best predictors were as follows:

1. Composed therapists work especially well when matched with schizophrenic patients who are anxious.
2. Therapists judged to be comfortable with aggression work well with hostile patients.
3. Grandfatherly therapists do well with seductive schizophrenic patients.
4. Therapists considered to be comfortable with depression do well with depressed schizophrenic patients.

In retrospect it also seems sensible that the optimism hypothesis proved to be predictive in the opposite direction, i.e., to the chronic patient who has a sense of failure, a charismatic or optimistic therapist may seem intimidating and dysjunctive. In future research we would retain this matching dimension but reverse the predictive direction. The results suggest that paying attention to these personality dimensions might help avoid particularly bad matches, increase the likelihood of good matches, and might provide guidelines to changing therapists when a case is not going well.

The results of both a multiple regression analysis and an intercorrelational matrix suggest that an overall dimension having to do with being comfortable, knowledgeable, and interested in the variety of intense affects of schizophrenic patients (anxiety, anger, sexual feelings, and depression) may be the central quality of successful therapists. This interpretation is supported in a recent study by Geller and Berzins (8), who concluded that A-type therapists may derive their effectiveness with schizophrenics from their greater tolerance for disturbed communications and behaviors. As a general statement, the present study suggests that in the absence of other more specific indications or contraindications, the presence or absence of this quality in a therapist can significantly influence the evolution of a therapeutic relationship and can even affect outcome. It should be emphasized that "comfort with" as used here does not imply distance but applies only in a context of involvement. This quality is one that can be expected to evolve from training, experience, and personal treatment, and this gives credence and direction to programs that intend to develop psychotherapists for work with seriously disturbed patients.

A conservative interpretation of the results is necessary because of the unique patient sample used (i.e., patients who during a long-term hospitalization required a change in therapist), because incomplete information meant that no predictions could be made on 33%–50% of the possible matches, because the validity of therapists as judges of the outcome variables is suspect, and because some therapist ratings were difficult to interpret.

It may be that successful psychotherapy for schizophrenic patients is contingent upon finding a good match between the therapist and the particular patient. The results invite further evaluation of the potential impact of the matching variable in evaluating psychotherapy of schizophrenia. If the positive findings of this study are borne out, the simplicity of ratings and the obvious clinical sense of the concepts used offer definite advantages over the A-B typology for therapists. More importantly, it offers a more rational approach to matching than leaving it to chance alone.

The Manfred S. Guttmacher Award

The American Psychiatric Association invites applications for its annual Manfred S. Guttmacher Award for 1979. The award is given for any outstanding contribution to the literature of forensic psychiatry in the form of a book, monograph, paper, or other work, including audiovisual presentations (films, etc.), submitted to or presented at any professional meeting or published during the period from November 31, 1977, to December 1, 1978. A plaque and an honorarium of $500 will be presented to the award recipient at the Convocation of Fellows at the 1979 APA annual meeting in Chicago, Ill. Please note that the award recipient is now required to give a lecture at the annual meeting.

Anyone who wishes may apply to receive the award by submitting five copies of the work as well as five abstracts to Carl P. Malmquist, M.D., Chairman, Guttmacher Award Board, 1700 18th Street, N.W., Washington, D.C. 20009. Entries will be acknowledged but will not be returned.

The deadline for submissions is December 1, 1978, and any entry to be considered must be in Washington by that date.

"No-Commitment Week": A Feasibility Study

BY ISRAEL M. ZWERLING, M.D., PH.D., HOPE R. CONTE, PH.D., ROBERT PLUTCHIK, PH.D., AND TOKSOZ B. KARASU, M.D.

To determine the extent to which involuntary hospitalization is overused, a "No-Commitment Week" was set aside, during which emergency room psychiatrists committed only patients in absolute need of hospitalization. Compared with the week before and the week after, there was no significant difference in the number of patients committed during No-Commitment Week. The authors propose replication of the study on a larger scale but suggest that decisions about involuntary hospitalization in public mental hospitals are the result of societal attitudes, which will be subject to change as long as society itself continues to change.

THIS REPORT addresses the controversy concerning involuntary commitment of patients to psychiatric hospitals, which continues to divide psychiatrists from each other and the mental health system from the judicial system. At one pole are those who argue that psychosis is an illness that permits a reliable diagnosis by appropriately trained physicians; that psychotic patients present a high risk of behavior that is dangerous to themselves or to others; that psychotic patients, precisely because of their psychoses, are frequently incapable of recognizing that they are ill and need treatment; and that the judgment that a person is psychotic and dangerous, and therefore in need of treatment, with or without consent, is one which a psychiatrist must be permitted to make without interference by any societal regulation or control beyond concurrence by a responsible member of the family of the patient.

At the other pole are those who argue that involuntary hospitalization represents a deprivation of liberty; that whatever the rationale for its justification it must remain, along with any other deprivation of liberty, an issue to be decided by the societal agency established for this purpose, i.e., the judiciary; and that, in any event, psychiatric diagnoses and the prediction of dangerousness by psychiatrists are highly uncertain and cannot be the sole basis for so harsh an action as involuntary hospitalization. That this controversy continues to be unresolved is eloquently attested to by the fact that 18 states[1] are currently revising or have in the past four years revised their statutes governing commitment.

The focus of this study is on involuntary commitment resulting from the certification by two psychiatrists that a person is mentally ill, dangerous, or both and in need of treatment. In reviewing the literature, it becomes apparent that many factors unrelated to the severity of a patient's illness come into play in the decision to hospitalize a patient on an involuntary basis. For example, there is a greater likelihood of involuntary hospitalization of individuals who have a history of psychiatric hospitalization and whose socioeconomic status is considerably lower than that of the interviewing physician (1). The likelihood is also greater for those individuals who appear at the hospital during weekends and evenings rather than during weekdays, times when the decision makers are usually residents rather than staff psychiatrists and when many of the family and community resources cannot be mobilized to aid the patient (2).

Perhaps the single most important determinant in the decision to involuntarily hospitalize a patient is the psychiatrist's perception of his or her dangerousness to others or to himself or herself. Rubin (3) reported that,

> Approximately 50,000 mentally ill persons per year are predicted to be dangerous and preventively detained. . . . In addition, about 5% . . . of the total mental . . . hospital population of the United States . . . are kept in maximum security sections on assessment of their potential dangerousness. (p. 397)

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Zwerling is Professor and Chairman, Department of Mental Health Sciences, Hahnemann Medical College and Hospital, 230 N. Broad St., Philadelphia, Pa. 19102. Dr. Conte is Research Associate and Dr. Plutchik is Director, Program Development and Clinical Research, Department of Psychiatry, Albert Einstein College of Medicine, Bronx, N.Y. Dr. Karasu is Director, Department of Psychiatry, Bronx Municipal Hospital Center, Bronx, N.Y.

[1]In the past four years, the following states have substantially revised their civil commitment laws: Arizona, Colorado, Florida, Hawaii, Michigan, Mississippi, North Carolina, Ohio, Pennsylvania, South Dakota, Virginia, Washington, West Virginia, and Wisconsin. In addition, Alaska, Illinois, Louisiana, New Jersey, and Oklahoma are considering substantial revisions; and in the following states, federal (f) or state (s) courts have invalidated all or major portions of the state civil commitment law in the past four years: Alabama (f), Hawaii (f), Iowa (f), Kentucky (f), Michigan (f), Nebraska (f), North Carolina (s), Pennsylvania (f), South Dakota (s), West Virginia (s), and Wisconsin (f).

Ennis and Litwack (4), however, present ample evidence to support the notion that violence toward either self or others is vastly overpredicted and that judgments made by psychiatrists are not sufficiently reliable or valid to justify nonjudicial hospitalization.

There can be little doubt that commitment laws and the machinery for involuntary hospitalization are open to overuse. Perr (5), to cite one recent example, reviewed the cases of 9 hospitalized psychiatric patients. In each case, an independent psychiatric review was requested by a private attorney, and results indicated that in 3 of the 9 cases mandatory hospitalization was not justified.

However, with the exception of extremists such as Szasz (6), who deny the concept of mental illness in its entirety, most concerned individuals would agree that there are situations when commitment of patients is necessary. There is also general agreement (7–10) that voluntary treatment is preferable to involuntary commitment under most circumstances. There is at the same time, however, the acknowledgment even by the most zealous civil libertarians that there are situations in which medical certification may be justified, for example, when a patient who is considered *imminently* dangerous to himself or to others refuses voluntary hospitalization or when a patient's very illness renders him incapable of making the judgment that he requires treatment. Nevertheless, as Ennis and Litwack (4) stressed, medical certification should authorize involuntary hospitalization only for the limited time needed to institute judicial proceedings.

The controversy over the issue of involuntary commitment centers, therefore, mainly on ways to ensure that the civil rights of psychiatric patients are not curtailed while at the same time satisfying the psychiatric profession's responsibility to provide care and treatment for those individuals who may be a danger to themselves or others or whose mental state is such that it is impossible for them to make a judgment concerning the need for hospitalization. It seems obvious that every effort should be made to obtain the patient's consent if hospitalization is deemed necessary. However, the limited amount of time usually available for a psychiatric evaluation in a busy psychiatric emergency room often precludes an adequate discussion with the patient of his or her problems and the reasons for hospitalization. Although administratively cumbersome, it is generally quicker to commit.

With these issues in mind, we undertook a pilot experiment at the Albert Einstein College of Medicine. The week of September 17–23, 1973, was designated "No-Commitment Week." The project was a study to determine whether it was possible to decrease substantially the number of involuntary admissions to Jacobi Hospital and Bronx State Hospital while at the same time providing appropriate patient care. This paper reports the procedures followed, the difficulties encountered in establishing such a week, the problems of implementation, the results obtained, and the questions that emerged.

METHOD

Jacobi Hospital is part of Bronx Municipal Hospital Center, which is affiliated with the Albert Einstein College of Medicine and contains a psychiatric emergency room and three inpatient wards, serving approximately 100 patients. Bronx State Hospital (now the Bronx Psychiatric Center) is a state facility serving approximately 700 inpatients and is also affiliated with the Albert Einstein College of Medicine. It also has extensive outpatient and satellite facilities. Each of these hospitals has its own admission office from which patients may be directly admitted. In addition, a number of patients are admitted to Bronx Psychiatric Center after having been evaluated at Jacobi Hospital and certified as mentally ill by two psychiatrists.

Before the project began, a detailed protocol was set up and efforts were made to notify all relevant staff members that for the stated one-week period commitment procedures would be altered. The basic plan was for the examining psychiatrist to try to persuade all patients believed to require inpatient treatment to accept voluntary hospitalization. Should the patient refuse voluntary hospitalization, the psychiatrist would then offer one or more of several alternatives to hospitalization: crisis intervention, day hospital, outpatient clinic, and home care service. Should the patient refuse these also, the psychiatrist was instructed to discharge the patient against medical advice, unless he believed that the patient was in absolute need of hospitalization. The guidelines for such an absolute need were as follows: "1) the patient has made a serious suicide attempt, is depressed, and still expresses a desire to kill himself; or 2) a patient has committed a serious homicidal or assaultive act and is concurrently diagnosed as psychotic; or 3) a patient has a serious disorganization of thought and behavior, has no place to go, and is unable to take care of himself." If the examining resident psychiatrist believed any one of these three criteria was applicable for a given patient, he or she was obliged to call one of four senior psychiatrists who were alone empowered to commit the patient. The "on-call" schedule for the four was posted in the admitting rooms of both hospitals, and the unit chiefs in each hospital were instructed that they were not to accept any patient during that week unless one of the four senior psychiatrists was a cosigner of the two-physician certificate. It was hypothesized that by making requirements for involuntary hospitalization more stringent the number of patients who would have been committed under usual circumstances would decline.

RESULTS AND DISCUSSION

Table 1 summarizes the data concerning the disposition of all patients who came to the admitting rooms of the two hospitals in the week before, the week of, and the week after the experimental period.

TABLE 1
Disposition of Psychiatric Patients

Disposition	Week		
	Sept. 10–16 (N=146)	Sept. 17–23 (N=153)	Sept. 24–30 (N=133)
Home	86	95	76

Bronx State Hospital	5	3	0
Total	14	6	3
Sept. 24–30			
Bronx Municipal Hospital	8	1	1
Bronx State Hospital	4	6	0
Total	12	7	1

The distribution of patients admitted to the wards of the two hospitals in the three time periods is summarized in table 2. There were no significant differences in the number of patients committed to the Bronx State or Jacobi Hospital wards during No-Commitment Week; these numbers are well within the normal range of week-to-week fluctuation at both hospitals.

This result was somewhat contrary to what we expected. The short period of time involved, one week, is not sufficient either to generate adequate numbers of patients for definitive results or to provide the many staff persons involved sufficient experience to insure complete familiarity with the protocol and to guarantee smooth implementation of the alternative dispositions when these are accepted by patients. For example, the senior psychiatrists said that in a small number of cases they would have made a greater effort to have patients who were committed accept crisis intervention services if they had had more confidence that the two crisis intervention teams could be relied on to immediately assume responsibility for the patients.

It may, of course, be hypothesized that the senior psychiatrists were themselves too locked into traditional criteria for commitment to permit any change, but given the focus of this study and the diligence with which each individual instance of an involuntary hospitalization was handled, we believe this simply was not the case.

In our opinion, the factor by far most responsible for these results is the resistance of public mental hospitals, perhaps in all cases but very markedly in the case of teaching hospitals, to admitting patients. Wilder and Karasu (11) recently described what they refer to as "the games institutions play," i.e., the devices employed to legitimize not admitting patients. Conversely, it has also been our observation that as soon as the census of a public mental hospital falls to levels that begin to provoke discussion of its not being needed—of its being phased out and closed—admissions increase and the census stabilizes or even rises. It would therefore be essential, in the planning of a future large-scale study, to take into full account the many nonmedical factors that bear upon hospital admission criteria.

Still another factor that surfaced during the present study as a potential danger in future studies is the geographic distribution of mental health resources in an area. Wilder and Karasu (11) were particularly incisive in their description of the "where-do-you-live" ploy, pointing out that a favorite device in dodging the issue of involuntary hospitalization of a floridly psychotic patient who appears to require treatment but refuses admission is to establish that the patient lives outside the catchment area or district for which the hospital is responsible. A total of 26 patients in our study were referred to other hospitals during the 3-week period under review—more than were involuntarily admitted to the Bronx Municipal and Bronx State Hospitals. It is readily conceivable that the data we have presented may have been significantly altered if the areas of residence of these 26 patients had fallen inside the boundaries of the two hospitals concerned.

Finally, a number of forensic issues were raised in the course of this study for which we can provide no answers and which would require serious attention in a more comprehensive study. To begin with, the legality of the very concept of "no commitment" was called into question by the residents covering the emergency room. What would be their position, they asked, if in the face of their professional judgment that a patient required involuntary hospitalization and in the face of a state law empowering them to commit such patients, they nevertheless refused and an unfortunate outcome resulted? Second, the issue of the validity of a voluntary consent for hospitalization was sharply raised. As

pointed out by Schwitzgebel (12), administrators and therapists often assume, quite incorrectly, that patients adequately understand consent forms. He cites, for example, a study by Palmer and Wohl (13) of 40 patients who signed voluntary admission forms for entry into a public mental hospital. Ten days after admission, 24 of the patients were unable to recall ever signing the forms, 14 did not recall the content of the form, and 2 patients denied having signed it. Schwitzgebel proposed a contractual rather than a consensual model for the protection of the rights of patients. It would appear, however, that a signed contract with an institution would be no more or less valid in terms of a patient's ability to understand what he or she has signed than would a signed voluntary consent form.

CONCLUSIONS

We were left with the impression that, at least in a university affiliated municipal or state mental hospital unit, the rigorous application of the most restrictive standards for involuntary hospitalization is not likely to produce a significant decrease in the commitment of patients. To the extent that there may remain the fantasy among civil libertarians that psychiatrists lurk in dark corners waiting to grab unsuspecting victims and commit them to extended stays in mental hospitals, this point should be emphasized. This study patently merits replication on a larger scale, perhaps statewide, for a longer period of time (perhaps a minimum of a month) and with adequate preparation of all staff members with regard to the issues concerned. It is possible that more informative data may derive from such a study. Our impression, however, is that decisions concerning the treatment of deviance in a society result from society's broadest attitudes regarding man's obligation to man and that a resolution of the question of involuntary hospitalization of mentally ill persons will be subject to change as long as society itself, and the structure and organization of its social roles, continues to change.

OPINION AND COMMENT

The Internship Year: A Negative View

BY SEYMOUR L. HALLECK, M.D.

The decision to add a fourth year of training with emphasis on a primary care internship experience has created serious problems for most psychiatric residency training programs. The logistic problems involved in having a department of psychiatry develop an internship program are formidable. The experiences being provided are less than optimum. Conceivably, the logistic and quality uncertainties that now characterize some PGY-I programs may be a factor in discouraging medical graduates from entering psychiatry. The reasons for moving to an internship experience are also questionable. There are no data which suggest that the new training will produce better psychiatrists. Nor can the case for the internship be supported by past experience or an analysis of the educational needs of today's psychiatrist. Dr. John Romano comments on the author's presentation.

I AM TROUBLED by the decision to require a fourth year or internship year of training in psychiatry for the following reasons. First, the decision was not made on the basis of data that supported a need for an internship requirement. Second, it has created formidable and as yet unsolved logistic problems for training programs. Third, some of the arguments used to defend the decision have been based on emotion and ideology rather than on a rational approach to meeting training needs.

THE LACK OF DATA

The failure of our professional organizations to generate or to examine data on the need for an internship year before making a decision to add that year was especially unfortunate. We do not know if those residents who were trained during a period when they were allowed to omit the internship experience and who elected to do so eventually became less, equally, or more competent psychiatrists than those who took an internship. Some anecdotal material did appear in the literature which suggested that residents who had not completed internships were having difficulties in caring for their patients (1). During the early seventies, however, accelerated programs that deleted even more years of training than simply the internship year reported that their rapidly trained residents were doing as well as or better than others (2, 3). My own informal effort to evaluate performances of residents with and without internships at the University of North Carolina indicated that those without internships were doing somewhat better. Of course, neither studies of a relatively elite group of trainees in a specialized program nor the observation of a single psychiatric training director can be viewed as significant data. My point here is simply that the limited information we did have at the time did not support the need to create a fourth year. It would not have been too difficult to generate more useful data. By 1973 there were large cohorts of doctors with and without internships who had received identical training in psychiatry, and the performance of these two groups could have been compared.

LOGISTIC PROBLEMS

The logistic problems created by the decision to put the internship requirement into effect on July 1, 1977, have been formidable. The new requirement comes at a time when federal funding for psychiatric training is being drastically curtailed. For many programs, alternative sources of funding are not available. Some programs have had to deal with this issue by reducing the number of residency applicants they accept annually. Further, implementation of the internship experience is being required at a time when the percentage of medical students applying for psychiatric training is

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2-6, 1977.

Dr. Halleck is Professor of Psychiatry, the University of North Carolina, School of Medicine, Division of Health Affairs, Chapel Hill, N.C. 27514.

0002-953X/78/0010-1202$0.45 © 1978 American Psychiatric Association

declining to a figure that may be as low as 4%. It is possible that the prospect of an additional year of training, often of dubious quality, may have been a critical factor in discouraging some graduates from applying for psychiatric residencies in 1977.

Major logistic problems developed when psychiatric training programs were required to discover positions for psychiatric trainees in old internship programs or to create positions in new programs. Psychiatrists do not have sufficient power to persuade university and community hospitals to spend time training psychiatric residents in primary care medicine. Departments of medicine, pediatrics, and family practice in medical schools have limited training facilities that are in great demand by residents who intend to stay in primary care specialties. In many instances, these departments have been unwilling or unable to cooperate in providing training experiences for psychiatrists. Only an occasional and highly fortunate psychiatric training program has been able to develop a quid pro quo arrangement in which the psychiatry department trains primary care physicians in psychiatry in exchange for the primary care department's training psychiatrists in medicine, pediatrics, and family practice. The logistic problem is less formidable in some large cities, where understaffed county hospitals welcome the addition of interns, whether or not they are going into psychiatry. However, there is some question as to the quality of the training experience these hospitals will provide.

Most departments have had some success in persuading community hospitals to provide primary care training for psychiatric residents. At this point, we have no way of knowing what the quality of teaching at these hospitals will be. Even if the experience proves to be good, community hospital training may impose additional types of hardships on the trainee. Many of the community hospitals that accept psychiatric trainees as interns are located as far as 30–100 miles away from the psychiatric training site. This is not a major inconvenience for an unmarried resident, but it can be a serious problem for a resident who has a family or whose spouse has a career.

As things stand now, there is little uniformity in the duration or quality of internship experiences in psychiatry. This is a source of great confusion to the applicant. It is also a problem for educators who are seeking to preserve standards of excellence in training and for accrediting agencies that will have to use a wide variety of criteria in evaluating the new programs.

There are also serious logistic problems in some programs insofar as the need to provide medical training for residents in postgraduate year one (PGY-I) will create at least temporary shortages of residents on traditional psychiatric services. Even the best psychiatric training programs require some service functions from their housefellows; but service positions cannot be manned when one-third to one-half of the fellows are on nonpsychiatric services. This is much less of a problem in relatively affluent programs that can recruit larger than usual classes, and some of the more creative of these programs began to provide an internship in July 1976. Other equally fortunate programs took two classes (PGY-I and PGY-II) in July 1977. However, in less affluent programs service responsibilities, particularly in the inpatient sector, may have to be taken over for at least a year by medical students, faculty, or second- and third-year residents. None of these alternatives is desirable, particularly the latter.

Disruptions in formal lecture and seminar schedules created by the internship year are minor but irritating problems. In programs that have created only four to six months of primary care internship training, a large proportion of the first-year residents—as many as one-third to one-half—will be unavailable for formal didactic instruction in psychiatry at any given time. This requires either twice as much teaching on the part of the faculty or a suspension or serious erosion of formal teaching activities in psychiatry during PGY-I.

CONCEPTUAL ERRORS

Some of the reasons for our professional associations initiating or endorsing the internship requirement have been rational. At a time when psychopharmacology is an integral part of psychiatric practice, it is essential that every psychiatrist be knowledgeable as to contraindications and side effects of psychotropic drugs. The more one knows about nonpsychiatric medicine, the more safely and efficiently he will use psychotropic medication. It is also true that some students in the many medical schools which shifted to an elective fourth year chose curricula that did not give them sufficiently broad medical knowledge. Many psychiatric educators worried that our medical school graduates were poorly prepared to assume patient care responsibilities. Adding a required year that includes some internship experience is certainly one way of trying to expand the medical knowledge of psychiatrists.

The internship requirement may also be self-serving; psychiatry is currently under attack from many sources, and most psychiatrists wish to sharpen their identity as physicians. A person or an institution under heavy attack relies on what is most familiar and dear when crucial decisions about third-party payment are about to be made and when other professions are competing with psychiatry for access to third-party remuneration, there is an additional advantage to allying ourselves as firmly as possible with our parent profession. Increased medical training requirements serve to identify psychiatry to the public, to politicians, and to other doctors as a medical specialty.

There have been other arguments put forward to defend the internship requirement that I believe are less than rational. In several years of discussing the internship issue with colleagues, residents, and medical students, I have repeatedly heard efforts to justify the need for the internship on the basis of two arguments. The first is that psychiatrists need to be more like other

physicians and, in particular, to develop modes of practice that are more similar to those of other physicians. The second argument is that much of the future role of psychiatry will involve consultation and liaison services to primary care specialists, and an expanded knowledge of nonpsychiatric medicine is absolutely essential if the psychiatrist is to adequately fulfill these roles. I believe the cases for both of these arguments are weak.

The first argument is extremely difficult to pin down. Its proponents often present it in almost mystical terms. The following type of statement is typical: "There is something about the endurance, the assumption of responsibility, and the performance of manual tasks required by an internship that makes one a better psychiatrist. There is something about the development of a sense of physicianship during the internship year that makes one a more mature psychiatrist." The "something" in these statements is never clearly defined.

A more understandable form of this argument is sometimes presented in terms of the psychiatrist's self-image. Psychiatrists want to be accepted by other physicians as esteemed colleagues. Often they are not. Many physicians do not consider psychiatrists to be "real doctors," and too many psychiatrists agonize over the possibility that their colleagues are correct. This situation has changed little in the 25 years I have practiced. There have always been a large number of physicians who are skeptical of the value of psychiatry and a large number of psychiatrists who are disturbed by that skepticism. One common approach psychiatrists have used to deal with the uncertainty of their role is to demonstrate that they can handle medical and surgical problems as well as other physicians can. An internship experience often assures the young psychiatrist that he is as capable of mastering medical and surgical skills as any other doctor.

I have little doubt that the internship experience may temporarily resolve the image problem for some psychiatrists. The "something" about an internship that is supposedly good for a psychiatrist may be an affirmation of his medical "machismo." If the psychiatrist is too insecure about his identity as a physician, he will either avoid certain medically ill patients or will be tempted to overcompensate for his perceived inadequacies by taking on medical tasks that exceed his skills. However, I doubt that this problem will ever be resolved simply by requiring an internship. Most of our psychiatric educators have had internships, but many are still preoccupied with their image as doctors. Psychiatric educators who are insecure about their own identity as physicians communicate this uncertainty to their students and keep them preoccupied with a medical machismo image. This unfortunate situation is also unnecessary. There is no reason for psychiatrists to feel that their style of practice either isolates them from other doctors or makes them less "medical" than other doctors.

Sometimes the argument that psychiatrists should practice more like other doctors is put in terms of the need of psychiatrists to return to the "medical model." Unfortunately, few who make such statements carefully define what they mean by the medical model. In its most basic form, the medical model simply means practice based on efforts to study pathological activities of the organism, to discover the causes of these activities when possible, and to intervene on an empirical basis when etiology is unknown or to treat the causes of pathological activity when etiology is more apparent. Within this broad definition of a medical model, there are many subtypes (4), which can be defined in terms of the manner in which etiologic variables are considered. In the most reductionistic and simplistic aspect of the medical model, attention is focused almost entirely on etiology related to biological dysfunction. In more sophisticated medical models, the practitioner focuses on multidetermination and the interaction of a variety of biological, psychological, and social factors in eliciting a given malfunction.

There is a certain efficiency and ease involved in adhering to a reductionistic medical model. Much of medical practice today is focused almost entirely on biological variables, and the nonpsychiatric physician rarely takes the time to investigate interpersonal or environmental variables. The physician is especially prone to ignore such variables during his early years of training as a house officer. An internship-type experience in most of the medical settings with which I am familiar will continue to emphasize a reductionistic medical model. This is not appropriate for psychiatrists. Psychiatrists should learn as much as they can about biological causes and treatments of emotional disorders, but training dominated by a model in which the physician is tempted to pay little attention to the complexities of interacting variables in producing emotional disorders is hardly desirable.

Psychiatric practice, or any effort to deal with the emotional problems of patients, requires an emphasis quite different from that currently being taught in most other branches of medicine. Even the capacity to make a good descriptive diagnosis and formulate a rational plan for treatment requires skills that are unlikely to be taught in most medical settings. The psychiatrist must have sufficient sociological perspectives to avoid overdiagnosing certain behaviors as pathological when they are actually manifestations of sociocultural phenomena. He must develop skills in dealing with patients who are uncooperative, resistant to treatment, and often ungrateful. He must develop a model of ascribing responsibility to patients for some of their actions and become skillful in using such a model to elicit behavioral change. He must learn to deal with patients who mimic, either consciously or unconsciously, symptoms of mental or physical illness and to view that mimicry itself as a symptom. He must take the time to develop enough rapport with the patient so that the patient will have sufficient trust to provide details on the phenomenology of his mental illness and the history of its development. Finally, the psychiatrist

must become comfortable in dealing with multiple variables in systems rather than a linear model of causality. These are not skills that are easily learned in an internship.

There is a great deal wrong with the profession of psychiatry, and some psychiatric practice can be careless and sloppy. However, when the psychiatrist is functioning efficiently and systematically attempts to integrate his observations and knowledge of multiple etiologic variables in understanding the patient, he is practicing the best medicine possible. To the extent that psychiatrists practice efficiently, we should not be trying to be more like other doctors. We should be urging other doctors to be more like us.

The argument that an expanded knowledge of nonpsychiatric medicine will make the psychiatrist a better consultant to his nonpsychiatric colleagues is often accepted at face value. Too many psychiatrists believe that our colleagues will more readily communicate with us and accept our recommendations if we can demonstrate that we have considerable knowledge in their own areas of expertise. Perhaps the best way of illustrating the weakness of this argument is to ask ourselves what we as psychiatrists are looking for when we call in an internist or a surgeon as a consultant. This is a role with which I have a great deal of personal familiarity because I run an inpatient unit and deal with many patients who have serious nonpsychiatric medical problems. When I seek consultation, I am looking for help from medical colleagues in areas in which I lack expertise. I want the internist to tell me about the patient's degree of cardiac pathology so I can assess the advisability of using tricyclics. I want the surgeon to tell me about the degree of stress and incapacitation that would result from a particular surgical procedure so that I can assess the manner in which the patient will be able to cope with it. The last thing I ever look for from a nonpsychiatric medical consultant is information about the patient's psychiatric status. I expect my consultants to treat the patient in a humane and compassionate manner, but I am not in the least concerned with their psychiatric skills. Occasionally, eager young consultants will comment on a patient's psychiatric status. Most of the time their assessments are grossly inaccurate.

I suspect that my medical colleagues are looking for the same thing in a psychiatric consultant that I look for in a medical consultant. They want someone who will help them deal with a situation in which they do not have expertise. They want a consultant who will assess the patient's degree of psychopathology and provide practical recommendations as to how to deal with it. Rarely will they welcome a consultant who spends a great deal of time discussing medical issues about which they already possess superior knowledge.

In recent years, an increasing number of internists have complained to me about younger psychiatric consultants who spend more time attempting to demonstrate their medical knowledge than providing psychiatric assessment and recommendations for psychiatric treatment. It is also interesting to note that teachers in some training programs in family medicine seem to develop an easier rapport with behavioral scientists, particularly psychologists, than with psychiatrists. Many family physicians prefer to consult with a psychologist rather than a psychiatrist. There may be several reasons for this phenomenon, but one explanation is that the psychiatrist is too preoccupied with his medical image and is less skilled than many psychologists in providing the family physician with psychiatric assessments and recommendations.

It is my hope that in the future, arguments for creating changes in psychiatric education will be scrupulously examined in terms of their logic, rationality, and logistic and political implications. Such an approach to change might even yield dividends in the near future. The current reality of a requirement of four years of postgraduate training in psychiatry is not entirely a burden. The extra training time can be put to good use if we are able to define what kind of nonpsychiatric medical and psychiatric medical experience are most essential in shaping a good psychiatrist. To do this, we must get back to the troubling question of defining a psychiatrist's task. We must develop a functional analysis of what services psychiatrists should provide. Once we can reach some consensus as to the psychiatrist's functions, training experiences in both psychiatric and nonpsychiatric medicine can be explicitly shaped to meet the trainee's functional needs. My expectations are that if we use such a rational approach, we will end up with a four-year program that puts minimum emphasis on traditional internship experiences.

Comment

BY JOHN ROMANO, M.D.

DR. HALLECK is troubled by the recent decision of the American Board of Psychiatry and Neurology to return to requiring a fourth year, or internship year, of preparation for psychiatry. I, too, have been troubled. However, my concern dates back to 1970, when the traditional internship requirement (the fourth year) was summarily eliminated (1). Since then, I have also been concerned with the sometimes valiant but quite unsuccessful attempts on the part of departments of psychiatry to design, execute, and supervise substitute programs to take the place of the freestanding rotating internship or the more extended residency preparation in medicine or pediatrics of the past.

Before responding to Dr. Halleck's ahistorical objections, I wish to point out that the psychiatric training program was a four-year program from the inception of the American Board of Psychiatry and Neurology in 1934 until 1970. Within that period the major eligibility requirements for candidates for certification were graduation from an approved medical school with the Doctor of Medicine degree; possession of an unlimited license to practice medicine in a state, commonwealth, or territory of the United States or a province of Canada; and one year of clinical internship. These requirements applied to all medical school graduates of the class of 1934 and subsequent classes.

The formal psychiatric training program after the internship was for a period of three years, followed by two years of practice before a person was eligible for examination. This schedule remained unchanged with the exception of several years after World War II, when the wartime internship of nine months was accepted as equivalent to the one-year internship.

In 1970 the one-year internship requirement was removed for M.D. candidates but not for D.O. candidates, and in the following year it was eliminated for both. In the intervening years (1970–1977) departments of psychiatry accepted candidates for their residency programs who 1) had traditional freestanding internship or residency preparation in medicine or pediatrics, 2) had no internship, and 3) were to be engaged in a four-year program variously constituted of assignments to medicine, pediatrics, neurology, and family medicine, often in hospitals distant from the parent department and usually with four months or more of psychiatric assignment to the parent department. In the 1977–1978 *Directory of Medical Specialists*, mandatory training requirements for physicians entering training programs on or after July 1, 1977, included two patterns (2). The first pattern includes the categorical and flexible first-year programs, which include experience principally in medicine but also in family practice or pediatrics. The second pattern is a four-year training program in psychiatry in which at least one year is to be spent in an approved program that provides direct responsibility for the general medical care of children and/or adults.

Dr. Halleck questions the wisdom of deciding to return to the internship requirement without sufficient evidence to make the change. This is the very point I made at some length eight years ago, when the decision was made to eliminate the internship requirement (1). He suggests that a survey could have been undertaken to evaluate and compare the performance of residents who had internships with those who did not. I believe such a survey would have little validity if it were based on self-report of the residents or on data obtained exclusively from those who conducted the residency programs. Bias would be almost insuperable because of self-selection and the very human trait of blessing what one has done, particularly in preparation for a professional career.

Objective tests for the acquisition and retention of information, knowledge, and certain skills, similar to those used by graduate boards, could be designed. I learned from Dr. Lester H. Rudy, Executive Director of the American Board of Psychiatry and Neurology, that no attempt has yet been made to compare the examination performances, in whole or in part, of those candidates for certification who had an internship and those who did not (personal communication, March 20, 1978). He indicated that this may be done in the future. Furthermore, at this moment (March 1978), Dr. Rudy does not have data on the number of applicants for certification who did not have an internship.

Obviously, to obtain both reliable and valid appraisals of the operational competence of the psychiatrist would require an intimate surveillance of the day-to-day judgments he makes in the study, care, and treatment of his patient and the patient's family—hardly an easy task. Furthermore, prodigious difficulties would be posed by the controls necessary for the systematic study of sufficient numbers of psychiatrists, with attention to their medical school preparation, the nature of the internship, the pattern of the residency, and current modes of diagnosis and treatment.

Dr. Halleck does not exaggerate when he recounts

Dr. Romano is Distinguished University Professor of Psychiatry, University of Rochester School of Medicine and Dentistry, Strong Memorial Hospital, Rochester, N.Y. 14642.

the formidable logistic problems encountered by departments of psychiatry in assuming responsibility for the internship assignment. We cannot know with certainty that the problems posed by the internship have had a major effect on the recruitment of medical students to careers in psychiatry. This is a highly complex issue undoubtedly influenced by many determinants, but it seems possible that the considerable confusion and obviously second-rate quality of many of the internships have contributed to the current recruitment problems.

Over the past several years our interns have shared with me their experiences, pointing out the patchwork quilt design of the internship, the considerable unevenness in the quality of the teaching and supervisory experience and in the nature and breadth of clinical experience, the feeling that they do not belong or are accepted with sufferance, and, most particularly, the distance, both geographic and intellectual, from the parent department of psychiatry. Furthermore, a number have been dissatisfied with the four-month psychiatric assignment during the internship year because they are asked to assume responsibilities, often in midyear, that are equivalent to those of the more informed resident and for which they have not been adequately prepared.

The assumption that the department of psychiatry would, or could, be in a position to supervise or be responsible for the internship assignment in medicine, pediatrics, neurology, or family medicine in hospital and clinic services at some distance is not only mistaken but patently absurd. When one considers how such an internship could be inspected, examined, or evaluated by review committees, one realizes how impossible is the task. One has only to remember how perfunctory and inadequate is the evaluation of psychiatric residency by the residency review committee.

Although Dr. Halleck is aware of the reduced clinical experience of our medical students as a result of the fourth-year elective opportunities and of the obvious need for today's psychiatrists to be more informed of psychopharmacology and of biological matters in general than were their predecessors, he takes issue with what he considers the most common justifications for the internship. In his view, these are 1) that psychiatrists need to be more like other physicians, and 2) that the future role of psychiatry will increasingly involve consultation and liaison services to primary care specialists. He challenges the general notion of the psychiatrist's learning to be a physician, believing that the idea of physicianship is often couched in mystical terms. He believes that psychiatrists are unduly concerned about their image as doctors and that psychiatrists would err should they adopt the medical model of the practicing physician. Dr. Halleck describes the extreme reductionistic aspect of the medical model, in which he believes attention is focused entirely on etiology related to biological dysfunction. Although he concedes that there are more sophisticated medical models dealing with multiple determinants and with the interaction of biological, psychological, and social factors, he believes that most medical practice is focused almost entirely on the simpler reductionistic model and, further, that the traditional internship may reinforce the reductionistic medical model, which he believes is inappropriate for the education of today's psychiatrist.

Evidently Dr. Halleck and I have had quite different experiences. It has never occurred to me that the lessons learned during the internship could lead to a mystical notion of physicianship. From personal experiences, from direct observations of several generations of interns and residents, and from their direct reports to me, I believe the contributions of the internship year to their professional education can be stated simply and clearly, with no vestige of mysticism. Eight years ago I asked each of our residents to write the five most important contributions of their internship experience, aside from the obvious increases in knowledge and skills about medical and surgical conditions. The following clusters emerged:

> a) significant change in his perception of himself, and his awareness of the perceptions of others that he is a physician; this was a different perception from that he had encountered as a clinical student; he became aware of assuming a new role in terms of responsibility, accountability, and dependability in the direct care of patients, engagement with families of patients, and learning how to work with others in the multiple set of the several health professions; b) repetitive application of theoretical knowledge to practical ends, responding to emergency needs, dealing with the dead and dying and with the reactions of their families; remaining responsible to a patient's charge in spite of fatigue, becoming more efficient and confident in problem-solving, decision-making, and planning daily activities; c) exposure to senior colleagues in the several medical disciplines and learning from them different styles, methods of approach, and the application of useful knowledge and technique; learning something of the problems of other medical persons in dealing with their patients; d) additions to one's store of knowledge about the significant psychosocial aspects of patients and their families, both the acutely and chronically ill, the convalescent and the disabled, learning something of the special problems of the battered or burned child and his parents, of the pregnant teenager, the anxiety of the middle-aged man with myocardial infarction, and the legion of other patients for whom the intern becomes directly responsible for study, care, treatment, and disposition; skill and confidence in interviewing and examining patients with somatic and psychological signs and symptoms with particular attention to the differential diagnosis of pain and disability; e) opportunity for full measure of determining choice of career, having kept options open, and learning of one's interests and aptitudes in the various fields of medicine; opportunity to engage in the teaching of medical students, nursing students, and others. (p. 1574)

More recently, in meeting with our current group of interns, much of the above was restated. The following statement of one of our interns (R.M. Fuchs, personal communication) is quite representative.

> Becoming an intern involves more than obtaining an M.D. after one's name. The task of the medical student is to make the transition from layman to physician by acquiring knowledge and becoming comfortable with the label 'doctor.' An intern, however, *is* a doctor. He is forced to make critical decisions, to be ultimately responsible for patient care, and to deal first-hand with death and grief—all with scarcely more wisdom than he had a year previously. The intern is the pivot around which revolve the patient, the attending physician, the senior house officers, the family, and the hospital. He must objectively integrate concerns that are often contradictory. The responsibility of coping with human suffering is a burden new to the intern. He must learn to get beyond his own emotional responses to sickness and death in order to deal effectively with his patients.

There can be no argument with Dr. Halleck when he indicates the inadequacies of the reductionistic biological model as an appropriate preparation for tomorrow's psychiatrist and, equally important, for tomorrow's physician. Perhaps Dr. Halleck would agree that the reductionistic psychological model espoused by many psychiatrists is also an inadequate preparation for tomorrow's psychiatrist and physician. There are those who defend the notion that all human distress is explicable in the paradigm of unconscious conflict and attempts at its resolution.

Obviously, modern biology, as well as modern medicine and psychiatry, can no longer be satisfied with simplistic reductionistic notions of health and disease, whether they emerge from infectious disease or from neurotic conflict. In fact, I have been impressed by the increasing sophistication of our medical colleagues in dealing intelligently and perceptively with multiple determinants of behavior and with the complex interrelationships of biological, psychological, and social phenomena, which play a part in the maintenance of health and in the emergence of disease. This is apparent not only among the clinical investigators in the fields of endocrinology, toxicology, metabolic diseases, and neoplasia but also with practitioners in their dealings with patients and their families. Like Gill (3), I have difficulty understanding what is meant by the medical model; I have even more trouble understanding what is meant by the "nonmedical model," whatever that may be. In operational terms, the medical model is often, if not usually, depicted as one in which the physician is active, authoritarian, and directive and the patient is compliant, passive, and in general nonparticipating. An example would be the administration of an antibiotic drug to a patient with an infectious disease, in which the body takes over and the patient, as a person, has no part. However, as we all know, within the medical model are those engagements between patient and physician in which the patient is encouraged and expected to take an active, conscious part in the treatment of his distress—for example, in modifying his diet, in self-medication, elective surgery, in bringing about changes in life patterns (smoking, recreation, responding to genetic counseling), etc. For that matter, in the nonmedical model, sometimes called the psychological model, there are approaches as authoritarian, if not more so, as any of the traditional medical models, e.g., behavior modification treatment and the interpretive judgments in psychoanalytic therapy. Therefore, in both models we can find the idea of patients passively accepting medication, advice, explanation of drugs, surgery, etc., but there are also other instances in which the patient must consciously and actively assume responsibility for behavioral change.

Clinical experience teaches us to be aware of the limits of usefulness of the Parsonian model of the sick role. This model was designed for those who are acutely physically ill and has not been useful in understanding patients with chronic medical and surgical illnesses or most psychiatric patients (4).

I am somewhat puzzled by Dr. Halleck's criticism of psychiatric consultation, and I wonder what relationship his comments have to the internship preparation of the psychiatrist. Psychiatric consultation is a skill to be learned during the residency period, and evidently those he criticizes did not have adequate preparation for their task.

On reflection, I am left with the impression that Dr. Halleck's negative view does not concern the internship exclusively but rather reflects serious reservations as to the usefulness of medical education in general in the professional training of the psychiatrist. If this is so, I would hope that he would clarify his position and explain more fully his reasons for these reservations.

I agree with one of Dr. Halleck's concluding remarks, when he insists that whatever changes we might make in psychiatric education should be informed, intelligent, and appropriate to the tasks of the psychiatrist as we perceive them today and as we may anticipate them to be tomorrow. The internship, no more than any other educational program, should never be considered a sacred cow. The curriculum is an instrument, a means to an end, never an end in itself, and is changed, as it should be, by the introduction of new knowledge and the acquisition of new skills. Furthermore, the internship cannot be dealt with in isolation because it will be affected by college and medical school preparation and, in turn, will affect materially the specialty training that follows it.

Surely there must be by now sufficient evidence to warrant significant revision of both undergraduate and graduate medical educational programs. It must be clear that the various experiments with the curriculum in the undergraduate period (particularly in those schools that established three-year programs) have led to diminished clinical experience and scholarship in recent medical school graduates. In the past the fourth year of medical school provided advanced clinical clerkships in all the major clinical disciplines, but with the change to an elective year, most students were deprived of the opportunity for sustained responsible clinical assignments. Thus, the assumption of the Millis Report—that the undergraduate clinical clerkship

would be sufficient to transform the student into a physician—has not been fulfilled, nor has the expectation that there would ensue institutional responsibility for graduate medical education (5). As a result, a considerable number of students face serious problems of transition between their role as students and their entrance into the formal specialty training program. This is particularly true for psychiatry, but it is also true for those who are interested in careers in anesthesia, pathology, dermatology, physical medicine, radiology, and perhaps others. These students wish to obtain a full measure of at least a year of clinical internship before they embark on their specialty training but have serious problems doing so because internal medicine, pediatrics, and family medicine, which would be primary in the construction of such internships, have unusually great demands on their resources. All of this has led, as most of us know, to students being forced to make early career choices when they are insufficiently informed. As a result, students often have to lie to convince program directors in internal medicine, pediatrics, and family medicine of a commitment of which they are really unsure. I am vigorously opposed to forcing students to make premature decisions. On an earlier occasion I wrote,

> I am not one who defends the thesis that there should be unbroken continuity between collegiate education, medical school, and graduate specialty training. I have learned that growth is hardly ever regular or even, and I would warmly support the occasional discontinuity or psychosocial moratorium that enables the student to free himself from the restrictions of the convoy system to examine more carefully his objectives and to plan more intelligently for his future career. Whatever changes may take place in the future, let us try to give our students every opportunity to make intelligent and informed decisions in their choice of career and special interest. This will require curricular planning, with full measures of scholarship in all fields relevant to their professional aspirations. (6)

I am heartened to learn that these matters are under serious consideration by the Council on Medical Education of the American Medical Association (7). With others, I hope sincerely that this group can enlist the interest and support not only of psychiatry's fellow sufferers in the clinical disciplines who face similar problems with what has been called the flexible internship but also the assistance and cooperation of those responsible for the primary care programs in medicine, pediatrics, and family medicine. One hopes, too, that these matters will engage the attention of the faculties of our medical schools. Only if there is a concerted attempt to correct the current deficiencies in clinical scholarship in the undergraduate period and the obviously deficient transitional flexible internship for the clinical specialties noted can we hope to ensure adequate standards for professional education.

As must be evident, I consider the internship, together with collegiate and medical education obligatory experiences in the professional preparation of the psychiatrist. I would hope that proper measures will be taken to ensure full measure of the internship assignment in terms of clinical experience and high standards of educational supervision.

BRIEF COMMUNICATIONS

Seclusion: Uses and Complications

BY MARLIN R. MATTSON, M.D., AND MICHAEL H. SACKS, M.D.

A total of 7.2% of the patients in a private psychiatric hospital were placed in seclusion during a one-year study. These 63 patients had a more frequent diagnosis of schizophrenia and manic-depressive illness, manic type, than a comparison group. Significant intergroup differences in age and length of hospitalization became insignificant when the seclusion patients under age 20 were excluded. Although seclusion was often used to protect patients, others, and property, the most frequent reason was to maintain a therapeutic environment. This study pointed toward a staff tendency to see the "problem" of the patient's behavior as being solved by seclusion rather than viewing seclusion as an intensive care environment in which the patient's behavior and treatment could be more carefully monitored.

THE SECLUSION ROOM is a regular part of most psychiatric units. Despite this, its use as a form of treatment for disturbed patients has received remarkably little attention. A computerized search of the psychiatric literature from 1964–1975 located only two relevant articles (1, 2), both of which viewed seclusion as an effective way of managing the destructive behavior of severely disturbed patients. Wells (1) reported that it was used with 4% of the patients admitted to a university hospital psychiatric unit but did not make any note of complications arising from its use. Fitzgerald and Long (2) commented briefly on the effects of staff disagreement on the use of seclusion, the importance of monitoring the patient's medical status, and the possibility that sensory deprivation might lead to a worsening of the mental state. One suspects that this paucity of reports on seclusion may relate to the discomfort of the psychiatric profession regarding its use. It is a topic that for personal, humanitarian, ethical, and legal reasons might lead to an avoidance of discussion and investigation. As part of a generalized review of the use of seclusion, we thought it might be useful to report our findings in order to stimulate discussion and establish directions for further study.

METHOD

A seclusion patient was defined as any patient who required the use of a locked seclusion room at any time during his or her hospitalization. All seclusion patients during 1975 were included in the study. The diagnosis, age, sex, marital status, length of hospitalization, reasons for seclusion, and complications of seclusion were recorded. These patients were then compared with a random selection of 160 nonseclusion patients during the same period. The hospital is a 104-bed private voluntary psychiatric division of a general hospital. It consists of six inpatient units, all of which are heavily staffed and involved in resident or medical student teaching.

RESULTS

During the period under study 63 patients (7.2% of the patient population) required seclusion. More than one-half of these patients (63%, N=40) were diagnosed as schizophrenic, compared with 38% of the nonseclusion group (N=61). The rest of the seclusion group received diagnoses of manic-depressive illness, manic type (17%, N=11), personality disorder (10%, N=6), and other (10%, N=6). In contrast, in the non-

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Mattson is Assistant Medical Director of the Payne Whitney Psychiatric Clinic of the New York Hospital, 525 East 68th St., New York, N.Y. 10021. He and Dr. Sacks are Assistant Professors of Psychiatry and Dr. Sacks is also Assistant Director of Residency Education, Cornell University Medical College, New York, N.Y.

The authors acknowledge with appreciation the statistical assistance of Mr. Peter Stoll. They also wish to thank Mses. Janet Kessler, Eleanore Rice, and Gilda Gatti for their assistance in the collection and tabulation of data.

TABLE 1
Types of Behavior Leading to Seclusion in a Sample of 63 Patients

Behavior*	Number of Patients	Percent of Episodes
Behavior disruptive to therapeutic environment	63	34.4
Assaultive to others	46	25.1
Threatening or verbally abusive	14	7.7
Destructive to property	14	7.7
Dangerous to self	13	7.1
Other	33	18.0

*Some patients exhibited more than one type of behavior.

TABLE 2
Complications of Seclusion in a Sample of 63 Patients

Complication*	Number of Patients	Number of Episodes
Assaultiveness	19	32
No note with each 24-hour period by primary therapist	16	26
Self-injury	8	10
Destruction of seclusion room	4	5
Deterioration of mental status	4	7
Deterioration of physical status	3	5
None	33	

*Some patients exhibited more than one complication.

seclusion group 4% (N=6) received diagnoses of manic-depressive illness, manic type, and 14% (N=22) personality disorder. These diagnostic differences were significant ($p<.01$, chi-square test).

Comparisons of sex and marital status revealed no significant intergroup difference. However, intergroup age differences were significant ($p<.05$, chi-square test). In the seclusion group the percentages for the 10–19, 20–29, 30–39, and 40 and over age groups were 24% (N=15), 29% (N=18), 29% (N=18), and 19% (N=12). Percentages for the nonseclusion group were 10% (N=16), 36% (N=59), 21% (N=33), and 32% (N=52). If the 10–19 age group is excluded, the age difference no longer reaches significance.

Patients who required seclusion had a significantly longer length of stay (58 days) than nonseclusion patients (38 days) ($p<.05$, t test). This significant difference disappears if patients aged 17 and younger are excluded. Table 1 lists the types of behavior that led to seclusion. The complications occurring during seclusion are shown in table 2.

DISCUSSION

The use of seclusion in our hospital was greater than that reported by Wells (1) (4% versus 7.2%). This difference may be even larger, since we defined seclusion as a locked room, which excluded quiet room patients. The differences noted may be due to patient population, staffing patterns, and attitudes concerning the use of seclusion. Greenblatt and associates (3) have documented how changes in staff philosophy can have a dramatic effect on the frequency with which seclusion is used. The general therapeutic philosophy on our units might best be described as a combination of psychopharmacology and expressive therapies (individual, group, and milieu). Seclusion is usually a last resort in helping patients to establish control of their behavior.

Diagnosis and age had a significant effect on whether a patient would be secluded. Schizophrenic and manic-depressive, manic type, patients tended to be secluded more frequently than others. These findings are in the expected direction. Age also had a significant effect on whether a patient would be secluded, but only if the 10–19 age group was included.

The mean length of hospitalization for patients who were secluded was significantly greater than that for patients who were never secluded. However, if one removes the adolescent patients from the seclusion group, the difference between the mean length of hospitalization for the adult seclusion group and the nonseclusion group is no longer statistically significant. Since the treatment program for adolescent patients emphasized a longer period of hospitalization, the fact that a patient required seclusion did not seem to provide an indication of the length of time he or she would need to be hospitalized. Similarly, neither sex nor marital status was significant in distinguishing seclusion from nonseclusion patients.

Although a patient requiring seclusion was more likely to be schizophrenic or manic, the data in table 1 provide more specific information regarding the behaviors that actually led to seclusion. Assaultiveness and behavior disruptive to the therapeutic environment were the most common reasons for seclusion. Examples of the latter behavior included repeated slamming of doors, running up and down the corridor unclothed, and persistent screaming. Although such behavior is not usually threatening to either the patient or others, it is the most frequent cause of seclusion. Disruptive behavior, as well as threats of assaultiveness, are areas in which staff attitudes toward psychotic behavior are very relevant in determining the frequency with which seclusion is used. Other variables that may affect the decision to seclude the patient and which require further study are staff-patient ratios, availability of staff, general anxiety on the ward, and staff training.

However, we have found that placing the patient in seclusion does not entirely restore the therapeutic environment of a ward. The rest of the patients remain apprehensive and concerned about the patient who is in seclusion. Fears regarding a similar loss of control or the inability of the staff to prevent such behavior from occurring are common themes during this time. However, the use of seclusion does enable the unit to place the patient in a quiet environment where he or she can be more closely observed so that frequent re-evaluation of the adequacy of the treatment plan can be made. At the same time the opportunities to hurt

oneself, to hurt others, or to damage the environment are minimized. These factors have led us to think of the seclusion room as an intensive care room, since it seems to be more appropriate to the needs of the patient at the time he or she requires its use.

We had hoped in the chart review to evaluate the effect of the seclusion room itself on the patient's behavior but could find no data to support either the traditional belief that removing a patient from the stimulating activity of a ward to a "quiet room" has a calming effect or the contrary hypothesis that the resulting sensory deprivation might produce further deterioration. What seems to occur is that a patient who is in seclusion is rapidly medicated while continuing the behavior that placed him or her there in the first place. The sedative and antipsychotic effect of the medication, combined with the patient's tiring himself out, may be the principal results of seclusion. This would be more consistent with the view that the seclusion room is not a treatment in itself but simply a place where intensive treatment can occur—an intensive care room. This approach enables the staff to more realistically appraise the function of the seclusion room and to explain its use to patients.

A surprisingly high number of complications occurred while patients were in seclusion (see table 2). One interesting complication was the tendency for the patient's therapist to provide less documentation of his or her involvement in the patient's total care. This was evidenced by poor documentation in the medical record of 1) evaluation of patients going into seclusion, and 2) reevaluation at intervals thereafter if seclusion needed to be continued. Although this absence of documentation is not a complication in the strictest sense, it could result in complications by not providing other staff responsible for the patient's care with information regarding the patient's behavior and the proposed treatment plan. These lacunae in the charts of seclusion patients could be related to a tendency toward the decreased involvement of some staff with the patient during this period or to uncomfortable feelings about placing a patient in seclusion. They seem to mirror the lack of attention to the secluded patient in the psychiatric literature.

We found that assaultiveness was also a common complication of seclusion, necessitating reevaluation of the patient's mental status and the adequacy of the current treatment plan. Seclusion alone is not sufficient to control assaultiveness. In over half of the occurrences, patients were assaultive to staff in the seclusion room. In slightly less than half of these episodes, the assaultiveness occurred while the patient was trying to leave the seclusion room when the door was unlocked by staff or, if the patient succeeded in leaving, during attempts to bring him or her back.

Self-destructive behavior was also a frequent complication. Despite staff precautions, some patients managed to take a sharp object into the seclusion room and others managed with great ingenuity to use the seclusion room itself to hurt themselves. Patients have unscrewed security light fixtures to expose electric wires and chipped tiles to obtain sharp-edged instruments. Of course, such assaultive or self-destructive behavior is often what caused the need for seclusion in the first place. However, it is clear that seclusion is not a "cure" but simply a more efficient way of enabling the staff to provide continued surveillance.

Those patients whose mental and physical status deteriorated in the seclusion room are worth further comment. One was a 53-year-old acutely schizophrenic woman who appeared to have a marked paradoxical response to chlorpromazine characterized by increasing confusion, agitation, and bizarre behavior that was not recognized immediately. The other patient was a 17-year-old boy who appeared to be acutely intoxicated and became assaultive when examined. Once in seclusion he became increasingly unresponsive. A sedative overdose was diagnosed and confirmed by gastric lavage. In both of these cases there was an unexpected organic complication that was not immediately considered once the patient had been secluded. In both situations there seemed to be a tendency to regard the seclusion room as a symptomatic treatment and the changes in behavior as temporary reactions to seclusion rather than as a progression of the symptoms that initially required the use of seclusion.

The danger in assuming that the seclusion room is a treatment in itself is that it may provide a false sense of security that the symptoms or their cause is being treated. This is also evident in our finding that many of the patients who deteriorated while in seclusion were not receiving adequate medication. The importance of repeated careful evaluations of the patient's mental and physical status, diagnosis (e.g., is there an organic component?), and the adequacy of current treatment once the patient is in seclusion must be emphasized.

CONCLUSIONS

In conclusion, we have found that 7.2% of the patients in a private psychiatric hospital were placed in seclusion. These patients had a more frequent diagnosis of schizophrenia and manic-depressive illness, manic type, than the nonseclusion group. Significant intergroup differences in age and length of hospitalization became insignificant when the under-20 age group was excluded. Although seclusion was often used to protect a patient from himself or herself, from hurting others, and from being destructive to property, the most frequent reason was to maintain a therapeutic environment. Staff attitudes and experience seemed to be a critical factor in this determination. The study of complications of seclusion pointed toward a staff tendency to see the "problem" of the patient's behavior as being solved by seclusion rather than viewing seclusion as an intensive care environment in which the patient's behavior and treatment can be more carefully monitored.

Marijuana Use in Schizophrenia: A Clear Hazard

BY DAROLD A. TREFFERT, M.D.

The use of marijuana as the independent variable produced a serious exacerbation of a psychotic process in four schizophrenic patients whose illness was otherwise well controlled with antipsychotic medication. Each patient served as his own control—the sole substance abused was marijuana and antipsychotic medication intake remained constant. Each time marijuana use at moderate levels began, there was exacerbation and deterioration. The author suggests that marijuana use is a special hazard to schizophrenic patients and that physicians should alert such high-risk patients to the possible untoward interaction between their illness and marijuana.

CONTROVERSY CONTINUES as to the degree of significant adverse medical effects of marijuana on various systems in the human body (1, 2). Medical/psychiatric studies thus far show that there is a temporal relationship, at least in some cases, between cannabis use and the occurrence of psychotic episodes (3–5). These episodes may be 1) toxic psychoses as a result of acute cannabis intoxication (6–12), 2) conditions resembling mania and dementia as a result of long-term cannabis abuse (10–13); or 3) paranoid psychoses resembling paranoid schizophrenia in the course of long-term cannabis abuse (13–15).

Questions remain regarding the number of cases (16), the dose relationship, if any (16), and whether marijuana causes a psychosis in an otherwise healthy person or whether it merely precipitates a latent psychosis in a predisposed person who already has significant premorbid psychopathology (5, 16, 17). While those controversies continue, surprisingly little attention has been paid to the important clinical observation that patients who are psychotic, irrespective of etiology, run the risk of relapse and exacerbation of an otherwise well-controlled illness by use of even moderate amounts of marijuana (3, 4).

Thacore and Shukla (18) found that 25 patients with cannabis psychosis responded swiftly to short-term antipsychotic treatment, and relapses occurred only when the patients reabused cannabis. Treatment was directed at preventing further abuse. To the already psychotic patient the use of marijuana in even moderate doses presents a clear medical hazard

I will describe four patients with well-documented schizophrenia in which the use of marijuana as the sole independent variable produced exacerbation of the psychotic process in an otherwise well-controlled illness.

CASE REPORTS

Case 1. Mr. A, a 23-year-old man, entered a general hospital psychiatric unit in June 1976 after severely mutilating himself with a razor blade. His first psychotic episode had occurred in January 1975, when he abruptly became profoundly withdrawn, stopped eating, could not sleep, and spent hours in bed in absolute silence with covers over his head to shut out all possible stimuli. He developed well-crystallized delusions, bizarre behavior, and a fulminating thought disorder. These symptoms followed his first involvement with smoking marijuana (two to three joints a day for a period of 2 months). He had no drug history and was not involved with any other drugs. There was a strong family history of mental illness—his paternal grandfather had committed suicide at age 40 and his maternal grandfather and a maternal uncle had been hospitalized for many years for psychiatric illness.

Mr. A, blatantly psychotic, catatonic, delusional, and periodically agitated, was hospitalized at that time (January

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Treffert is Director, Winnebago Mental Health Institute, Winnebago, Wis. 54985.

1975) for approximately 2 weeks. He impulsively left the unit and threw himself in front of an automobile, seriously injuring himself. He was then transferred to a state hospital, where he remained for 4 months. He was released on fluphenazine enanthate and was maintained at home on an outpatient basis. He was generally active and alert and resumed his drawing and painting, which he was involved in prior to his first psychotic episode. He participated in athletics, slept well, and did some socializing.

In May 1976, 2 weeks prior to his second admission to the hospital, Mr. A began using marijuana heavily (at least three times daily on a regular basis) and was on what he described as a "2-week trip." He used no chemicals other than marijuana, used no alcohol, and continued to take his psychotropic medication. It was following the "2-week stoned trip" that Mr. A mutilated himself. At admission he was frightened, startled, and nearly mute; showed remarkably flattened affect; and was hallucinating and delusional. The self-mutilation occurred as part of an extensive delusional system involving God, the devil, and bisexuality.

The patient was hospitalized for 3 months and responded to a combination of electroconvulsive therapy and high doses of psychotropic medication including haloperidol, trifluoperazine, chlorpromazine, and amitriptyline. With regular medication and without marijuana, the remission has been maintained over 18 months. Mr. A attributes his relapse to the resumption of marijuana use even though he had been taking his psychotropic medications regularly.

Case 2. Mr. B, a 21-year-old Marine, began using a variety of chemicals, including marijuana, lysergic acid diethylamide (LSD), mescaline, and heroin, while overseas. He admitted to heavy use of cocaine and LSD. In July 1975 he was shooting methylenedioxyamphetamine (MDA) at a party, and also was taking pentachorlophenol (PCP). Shortly thereafter he was hospitalized with a "toxic psychosis," which included bizarre and manic behavior, severe agitation, a profound thought disorder, and a well-crystallized delusional system. There was obvious liver impairment as well, with SGOT levels of 1280 units. He was hospitalized on the psychiatric unit of a general hospital for approximately 4 weeks and responded slowly but regularly to high doses of fluphenazine decanoate, thioridazine, and haloperidol. His fragmented thinking slowly cleared, and his confusion and the delusional system disappeared.

He was discharged reasonably symptom-free but on high doses of psychotropic medications. The delusions and hallucinations had disappeared completely. Mr. B did well for 3 months but then began to smoke marijuana "to help his depression." Nevertheless, he continued his psychotropic medications regularly as prescribed. Following the resumption of daily marijuana smoking, his condition deteriorated and his delusional system promptly returned, requiring rehospitalization in February 1976. He remained in the hospital approximately 3 weeks, during which time his symptoms again were relieved; he then returned to outpatient status.

During the months following, Mr. B followed the prescribed medication regimen but periodically resumed the use of marijuana (no other chemicals or alcohol). Each resumption of marijuana use was correlated with a deterioration of his condition—a return of an obvious thought disorder, ideas of reference, preoccupation, staring, and withdrawal to bed for hours at a time. When counseled about the need to avoid marijuana, he would stop use of the substance and his symptoms gradually would clear. After several such episodes he agreed with the observation that marijuana was toxic to him; for the next 6 months he did not use marijuana and his psychotic symptomatology did not recur. He continues to take his psychotropic medications regularly, is working, and is free of his ideas of reference and delusional material. He is much more active, socializes well, and shows no evidence of a thought disorder.

Case 3. Mr. C was first hospitalized for approximately 5 months at age 15 for treatment of a severe schizophrenic illness characterized by catatonic symptoms, profound withdrawal, and disorganized thinking. He was maintained on antipsychotic medication and was seen on an outpatient basis over a period of approximately 36 months. At age 18 he required rehospitalization following discontinuation of medication and experimentation with, and then daily use of, marijuana. That hospitalization lasted nearly 9 months before the agitation, paranoid delusional system, and bizarre behavior subsided sufficiently for Mr. C to be released on intramuscular fluphenazine decanoate.

Mr. C did well for approximately 4 months. However, he resumed smoking marijuana heavily 2 weeks prior to his third hospitalization; at the time of his admission he turned in his "grass," pipe, and a supply of marijuana to the admitting doctor. For those 4 months between hospitalizations Mr. C was maintained on intramuscular fluphenazine decanoate. At admission he was frightened, anxious, paranoid, agitated, and again showed obvious thought disorder. He had a series of electroshock treatments to which he responded favorably; after 6 months he was released on piperacetazine and lithium carbonate. As an outpatient, Mr. C did quite well; he resumed work, became more socially active, and showed no evidence of his delusional system or thought disorder. His affect remained somewhat flattened. Mr. C continued regular intake of his prescribed medications; however, he resumed the use of marijuana in order to establish better social relationships with his friends, who were using marijuana on a regular basis. He slowly began to deteriorate again and experienced withdrawal, ideas of reference, agitation, and insomnia. He admitted that he had been using marijuana again in order to feel less depressed and more socially acceptable. Over the next 18 months Mr. C had episodes during which his illness deteriorated, and each of these was correlated with the resumption of marijuana, in spite of regular intake of psychotropic medications. In February 1976, the patient began to use marijuana very heavily and became hyperactive, explosive, uncontrollable, and finally had to be transferred to a maximum security hospital. He remained in that setting for approximately 4 months. After the delusions and agitation ceased, he returned home on lithium and trifluoperazine, which he has continued regularly. He has maintained his remission for approximately 4 months, and since he has concluded that the marijuana was responsible for his deterioration, he has not resumed its use.

Case 4. Mr. D, a 24-year-old man, was first seen in July 1973, after a period of progressive depression and disorganization. In the 3 months prior to admission he had been increasingly confused and disoriented, with disorganized thinking. At the time of admission he was disorganized, his associations were loose, and there was an obvious thought disorder. He was agitated, sobbed and cried uncontrollably, and experienced a great deal of sexual preoccupation and bizarre ideation. Mr. D indicated that he had been using psychedelics heavily and had taken LSD or mescaline on more than 100 occasions. He also admitted to heavy use of marijuana and the use of amphetamines. He responded fairly

promptly to fluphenazine decanoate and trifluoperazine and was followed on an outpatient basis.

After 12 months the medications were gradually decreased. Mr. D finally discontinued both the medication and outpatient contacts. He began graduate school 12 months later and also resumed the use of marijuana. He indicated that he was smoking approximately three to four times per week but was using no other drugs or chemicals. He became increasingly agitated, developed a fairly elaborate delusional system, and went to New Jersey to meet with the president of the United Nations. Mr. D became acutely agitated on the plane to New Jersey and continued to have delusions; after an unplanned stop he was hospitalized at a county receiving hospital and was frankly delusional and psychotic. When he finally was transferred to a hospital near his own home, Mr. D was preoccupied and distant. He spoke slowly and deliberately and talked about his ideas of reference and a fairly expansive delusional system. He indicated that he had resumed the use of marijuana. Mr. D was placed on psychotropic medications and responded well to them. His thinking cleared, he became less preoccupied, and he was discharged on a combination of fluphenazine decanoate, haloperidol, and diazepam.

DISCUSSION

I have not presented these four cases to draw any conclusions regarding the relationship between onset of the original psychosis and the use of marijuana, although there was a temporal relationship between the use of marijuana and the onset of psychosis in each patient. It should, however, be noted that other drugs were involved in the original onset in at least two of the cases and that in one case there was a strong familial incidence of major mental illness.

Instead, these cases illustrate that in schizophrenic or otherwise psychotic patients whose illness is well-controlled with medication, the use of marijuana is a clear hazard, irrespective of etiology of illness or involvement of drugs in onset. Patients who use marijuana run a risk of exacerbating an otherwise well-controlled illness. In each of the four cases the patient served as his own control; i.e., marijuana was the only substance used, and each time the patient resumed use of marijuana at moderate levels (on his own volition and against medical advice), his illness was exacerbated. Abstinence from marijuana led to improvement and stabilization.

All four patients are still under treatment, and each has become convinced, through persuasion and his own observation, that marijuana use is clearly correlated with recurrence of psychotic symptoms. Each of the four patients now abstains entirely from marijuana use, and remission has been sustained. One patient describes marijuana as "ungluing" him, and another talks about it being "toxic" to him. Nevertheless, during rehabilitation each has felt a temptation to use marijuana to deal with the depression frequently felt after a major psychotic episode and/or to reestablish better social relationships, particularly if prior to hospitalization the patient was involved in a peer group where marijuana use was frequent. The schizophrenic patient is at high risk with respect to marijuana use. Perhaps some persons can safely use marijuana, but schizophrenics cannot. This special risk of marijuana use to the 500,000 schizophrenic persons in the United States has obvious and far-reaching implications.

The schizophrenic patient must be alerted to the special hazard of marijuana use for the same reasons that the patient on tranylcypromine must be alerted to the special hazard of foods with high tyramine content or the patient with porphyria to the special hazard of barbiturates. It is the physician's responsibility to alert all high-risk patients about the possibility of experiencing untoward interactions between their illness and the substances they use.

Popping and Snorting Volatile Nitrites: A Current Fad for Getting High

BY LEONARD T. SIGELL, PH.D., FREDERIC T. KAPP, M.D., GREGG A. FUSARO, E. DON NELSON, PHARM.D., AND RUSSELL S. FALCK

In certain social circles a variety of volatile nitrites are being used extensively to expand creativity, stimulate music appreciation, promote a sense of abandon in dancing, and intensify sexual experience. Soon after amyl nitrite (the prototype of this group) became a prescription drug, legally produced substitutes appeared and were sold as room odorizers. Analyses of eight of these substitutes showed them to contain isomers of butyl or amyl alcohol and a corresponding nitrite. The authors describe the context of use of these products and their desired and adverse effects.

AMYL NITRITE and other volatile nitrites have become popular street and over-the-counter drugs that are inhaled to alter consciousness, enhance meditation, stimulate dancing, and intensify sexual experience among certain groups of the population. They are examples of mankind's never-ending search for behavior-influencing agents that will produce a state of ecstacy with the utmost enjoyment of all desires and passions. Although a variety of psychological and physical approaches to this end have been and still are in vogue, such as transcendental meditation and yoga, the most popular means to achieve an altered state of consciousness and hoped-for expanded creativeness and hyperacuity of sensation has been the use of chemical substances. The list of such substances is endless, varying from ancient man's use of the poppy and fermented fruit juices to such current customs as smoking marijuana; snorting cocaine; mainlining heroin; ingesting downers, uppers, hallucinogens, and deliriants; sniffing glue; and, recently, inhaling volatile nitrites.

Our interest in the effects of and potential for harm associated with acute or chronic inhalation of volatile nitrites came about because of questions posed to two of us (L.T.S. and E.D.N.) who are involved with the Cincinnati Drug and Poison Information Center. The center is a hotline program that responded to 36,000 phone calls during 1976 (80% from the public). Several callers (especially users, staff of community mental health centers, and psychiatrists) wanted information about the contents of these products and their possible adverse effects.

In order to obtain information that would allow us to respond to these inquiries we conducted a literature search, analyzed the contents of several samples, and collected additional information from several users of these agents. (We submitted this paper to the *Journal* on September 9, 1977.)

BACKGROUND

Amyl nitrite has been used medically since 1867 to provide relief from attacks of angina pectoris (1). It is packaged in small, thin glass capsules covered by cloth webbing that can be easily crushed between the fingers and the fumes inhaled when the patient suffers anginal pain. In the late 1960s sales of amyl nitrite rose sharply due to its nonmedical use as an agent for getting high and as an aphrodisiac. It acquired the street name "poppers" because of the sound created when the capsules were crushed just before inhalation of the amyl nitrite fumes.

Since amyl nitrite was made a prescription drug in 1968, other liquid volatile nitrites have been marketed in bottles containing 10–30 ml and selling for $3–$10 each. Until recently male homosexuals indulged in these drugs more than other groups did. They would inhale the vapors just at the time of sexual orgasm, claiming that this enhanced their sensation. One author claimed that "poppers" are inhaled during anal intercourse by the passive partner, presumably to relax the anal sphincter and thus facilitate intromission (2), but they are also used by either partner in association with any sexual act.

During the past two years the use of these drugs has increased considerably among heterosexual men to supposedly enhance orgasm, as well as among both sexes, often in groups, just for getting high. Indulgers often take them in social situations, particularly to promote a sense of abandon in dancing, expand creativity, stimulate music appreciation, and enhance meditation.

0002-953X/78/0010-1216$0.40 © American Psychiatric Association

Common settings in which these agents are used include the bedroom, parties, backrooms of pornographic bookstores, pornographic theaters, bars, and dance floors. Some users have told us that a few discotheques use special lighting effects to indicate that they are about to spray nitrite fumes over the dance floor.

The snorting of volatile liquid nitrites for hedonistic purposes in recent years has created a large business estimated to total $50 million a year. Sales have reportedly averaged 100,000 bottles a week in one city alone (3). These substances are advertised in underground newspapers and flashy sex magazines, purportedly to be used as room odorizers to produce such supposedly aphrodisiac odors as the smell of a gymnasium. Since their labels state that they are not to be inhaled, they are sold legally over the counter in various pornographic shops, novelty or "head shops," or by mail order under such suggestive trade names as Heart-On, Jac Aroma, Locker Room, Bullet, Rush, Aroma of Men, Toilet Water, Ban Apple Gas, and Crypt Tonight. Unlabeled preparations produced by small manufacturers are also found in many cities. To their users they are all known as either "poppers" or "locker room." They are inhaled directly from the bottle or by way of single or double nasal inhalers.

The pleasurable sensations that are perceived from the inhalation of the volatile nitrites as well as from the other chemical agents used to affect mood, perception, thought, or behavior result from the combined effect of the pharmacology of the specific agent, the individual's expectation of what it will do for him or her, and the environment or social setting in which it is used. The consequences of drugs taken for purposes of affecting the mental apparatus are strongly influenced by the reputation they have among their advocates as to what effects they are supposed to have on one's psyche and behavior.

Most of the users we talked with were willing to discuss freely their experiences with these agents. Some expressed preferences for specific products, citing either a favored aroma or a stronger effect. Some reported experiencing prolonged pulsatile headaches and dizziness. Others claimed that they were no longer able to perform sexually without the use of these drugs.

CHEMISTRY AND PHARMACOLOGY

To determine the contents of currently available volatile nitrite preparations, we analyzed six brand-name products and two unlabeled street samples. The results indicated that six of the samples contained an isomer of butyl alcohol, two contained an isomer of amyl alcohol, and all had a corresponding nitrite.

We conducted an extensive search of the biomedical literature and found a paucity of clinical reports describing adverse effects from acute and/or chronic inhalation of these agents. Because of amyl nitrite's 111-year history of medical use in relieving symptoms of angina, far more is known about its systemic effects than about the effects of isomers of amyl and butyl alcohol and butyl nitrite.

Butyl nitrite was investigated in the late 1800s as an alternative to amyl nitrite for patients with angina (4). It has essentially the same therapeutic effects as amyl nitrite but has not been used clinically to any extent. Both amyl and butyl alcohol are used as synthetic food flavoring materials, the former in fruit and liquor flavors and the latter in rum, liquor, and butter flavors. Data, primarily from animal studies, suggest that small quantities of these alcohols do not produce toxic effects.

The following is a summary of the published effects of inhaling the ingredients in these products (5-8).

Central nervous system: light-headedness, weakness, nausea, ataxia, delirium, headache (both short-lived "nitrite headaches" and prolonged pulsatile headaches), syncope (following profound vasodilatation), tolerance, sedation, and anesthesia. (The last two effects are from reports of animals exposed to high concentrations.)

Cardiovascular: profound hypotension and cutaneous flushing followed by reflex vasoconstriction and tachycardia, and transient ECG changes (e.g., inverted T waves and depressed ST segments).

Hematological: methemoglobinemia (documented after oral and parenteral administration and repeatedly mentioned as a possibility after inhalation, but no reports were found when it occurred in association with the hedonistic use of these substances) and normocytic normochromic anemia after exposure in an industrial setting.

Ocular: increased intraocular pressure (reported but quite unlikely) and supraorbital pain.

Pulmonary: irritation (from reports of animals exposed to high concentrations).

We could find little information about the doses and duration of exposure necessary to produce the more serious adverse effects. Most of the toxicology literature on butyl nitrite and amyl and butyl alcohol refers to concentrations in the air breathed by industrial workers.

Research regarding N-nitrosation reactions (9) raises the issue of whether repeated use of these products could increase the risk of developing cancer. Inhaled nitrites could interact freely with endogenous trivalent nitrogen compounds to produce nitrosamines. Some nitrosamines are known to be carcinogens. It remains to be determined whether nitrosamines are formed after inhalation of these preparations. If so, are they carcinogenic, and how much exposure by inhalation would be required to produce them in amounts sufficient to increase the risk of cancer?

Comparing Arrest Rates of Mental Patients and Criminal Offenders

BY HENRY J. STEADMAN, PH.D., DONNA VANDERWYST, M.A., AND STEPHEN RIBNER

The authors compared the arrest rates of former mental patients with those of criminal offenders released in the same jurisdiction. The data for all ex-patients and all offenders released in Albany County, New York, in 1968 and 1975 support the contention that it is the relationship between prior and subsequent arrests that explains the increasing crime rate of ex-patients and the three to six times higher rate of arrest of released offenders. Since the three-quarters of former patients with no arrest records were arrested about as often as the general population and substantially less often than offenders, care is warranted in drawing inferences from overall mental patient arrest rates.

IN THE PAST DECADE the literature dealing with the arrest rates of former mental patients (1–10) has burgeoned. This interest appears to be linked to concerns that expansion of community treatment programs has placed or kept in the community more persons who are violent or apt to be involved in criminal activity. In addition, this growth of research literature has been fueled by the finding in all studies published since 1965 that former patients are more often arrested for certain offenses than the general population. In all of these studies inferences have been drawn from differences observed between the patient rates and those of the general population in the states, counties, or catchment areas from which the patient samples were taken. Given our recent analysis of New York State data (11) suggesting that prior criminality rather than mental illness may be the root cause of these differences, it may be more instructive for the development of social policy to compare patient arrest rates with those of criminal offenders released in the same jurisdictions.

Despite the increasing number of studies about arrest rates of ex-mental patients, none has provided such comparisons. In this report, we will examine the experiences of two groups of released patients and two groups of released offenders in Albany County, New York, as a first step in determining of what use such comparisons might be in addressing the volatile issues of the criminal behavior of former mental patients.

METHOD

In order to make some preliminary assessment of the stability in any identifiable trends, we selected two groups of released mental patients and two groups of criminal offenders. We studied all Albany County residents released from New York State psychiatric centers in fiscal 1968 and fiscal 1975; there were 307 in 1968 and 204 in 1975. The criminal offenders studied were all the offenders released in fiscal 1968 and 1975 from the Albany County jail and all Albany County residents released in calendar 1968 and 1975 from state

TABLE 1
Arrest Rates for Albany County Released Mental Patients and Criminal Offenders and New York State General Population

Group	1968 Arrests per 1,000		1975 Arrests per 1,000	
	Total	Violent Crimes	Total	Violent Crimes
General population	27.53	2.29	32.51	3.62
Ex-patients	77.98	2.05	111.18	12.35
Criminal offenders	267.84	22.63	695.00	87.50

TABLE 2
Arrest Rates for Albany County Released Patients and Criminal Offenders and New York State General Population, by Number of Prior Arrests

Group	Arrests per 1,000	
	In 1968	In 1975
General population	27.53	32.51
No prior arrests (patients)	27.63	37.89
One prior arrest		
Patients	52.50	120.00
Offenders	151.20	378.00
Multiple prior arrests		
Patients	297.82	302.40
Offenders	275.07	729.91

prisons. There were 167 offenders released in 1968 and 252 in 1975. All mental hospitalization records for both the mental patients and offenders were obtained from the Department of Mental Hygiene's data processing unit. All criminal records for both groups were obtained through the collaboration of the New York State Department of Criminal Justice Services.

The offender groups in both years were predominantly male (93% and 90%, respectively) compared to the released mental patient groups, which were 52% and 61% male. Likewise, the offenders tended to be younger and more often black than the mental patients. Since the purpose of this paper is to examine the comparative arrest rates of all released mental patients and all released offenders in the same jurisdictions, the potential impact of these group differences in the observed rates will not be examined. Our intention is simply to answer the question of how the rates of arrest of ex-patients and offenders compare.

FINDINGS

As is shown in table 1, as expected, in both 1968 and 1975 the released mental patients overall had substantially higher arrest rates than the general population. For both years, however, the offenders' rates were much higher than the mental patients'. In 1968 the mental patients' overall arrest rate was about three times that of the general population, but the offenders' rate was about three and a half times that of the mental patients. Also, in 1975 the mental patients' total arrest rate was about four times that of the general population, but the offenders' was six times that of the mental patients. For the most part, the same trends exist for violent crime except that in 1968 the mental patients were arrested somewhat less often than the general population. In both years the offenders were arrested much more often for violent crime than the mental patients. Because of the infrequency of violent crimes among the former patients, the limited size of our two samples did not permit more detailed analyses except for total arrest rates.

While the total rates reported in table 1 are important—particularly the consistently higher rates of arrest for offenders than ex-patients—there is a critical relationship for both the mental patients and offenders that these rates mask. As was found in our earlier work (11), among the ex-patients there were dramatic differences in arrest rates depending on whether they had been arrested prior to the current hospitalization. As is evident in table 2 this same relationship existed in the two patient samples from Albany County and among both the 1968 and 1975 offender groups. The ex-patients who had no arrests prior to their current hospitalization were arrested about as often as the general population. For both 1968 and 1975 those mental patients and offenders who had one arrest prior to their release were arrested substantially more often than the general population, and those with multiple prior arrests had exceedingly high arrest rates after release. Since all of the offenders had at least one prior arrest at the time of their releases, there are four combinations of year and number of prior arrests (one or multiple) according to which mental patients and offenders can be directly compared. In three of the four comparisons the offender group remains higher, but in the multiply arrested 1968 releasees the corrections group is lower. Because the trend toward higher arrest rates is completely consistent with a higher number of prior arrests, it seems that the relationship between prior and subsequent arrest explains the overall differences reported in table 1 in the offender and mental patient rates rather than something else associated with the offender.

In most comparisons between the arrest rates of mental patients and the general population, the mental patients will be more often arrested. This is primarily because a much higher percentage of those persons currently being released from state mental hospitals have been arrested previously than is the case among the general population, and it is true that in any population there is a very strong relationship between having been previously arrested and being subsequently arrested. Likewise, then, when the arrest rates of mental patients are compared with those of released offenders, it is not surprising that the offenders have consistently higher rates of arrest than the mental patients. The offenders all have been arrested at least once and we have seen that among mental patients with one prior arrest their rates usually slightly exceed those of the general population. Also, a much higher proportion of the offender group has multiple prior ar-

rests, which greatly increases the probability of future arrests.

DISCUSSION

These data drawn from one county in New York for two time periods would seem to support the conclusion that as the composition of state mental hospitals has changed to include more persons with prior police records, the rate of arrest of former mental patients has increased and now exceeds that of the general population. What the comparative data on the criminal offenders released at the same time into the same areas provide for the first time is documentation that, as the proportion of any population with previous criminal records increases, so too will their rate of future criminal activity. It would appear that the use of the arrest rate data of former mental patients in policy discussions revolving around the controversial issues of deinstitutionalization and the "dumping" of mental patients must be more specifically formulated in terms of subgroups of mental patients and the changing composition of the populations being released. Those mental patients who have not been arrested—approximately three-quarters of all released patients in New York—are arrested about as often as or less often than the general population. It is the multiply arrested mental patient who is often arrested after release. Thus, when a geographically comparable group of offenders is used for comparison, the rates of released mental patients become much less intimidating, and it becomes evident that there is a need for more appropriate points of reference than the general population for comparing the rates of ex-patients given the changing composition of state hospital clientele.

The issue is not so much that there are more mentally ill people at risk for criminal activity in the community; more accurately, the problem seems to be that there are more criminals in mental hospitals in the first place.

Supplemental Security Income and the Sick Role

BY H. RICHARD LAMB, M.D., AND ALEXANDER S. ROGAWSKI, M.D.

Supplemental Security Income (SSI) has given the psychiatrically disabled a dependable source of income and helped make it possible for them to live outside state hospitals. The change to SSI has had an important effect on delabeling and decreasing the stigma of receiving Aid to the Disabled. However, the secondary gain inherent in SSI may interfere with social and vocational rehabilitation efforts. The authors present recommendations aimed at making the SSI system more conducive to social integration and rehabilitation.

FOURTEEN YEARS have passed since eligibility for Aid to the Disabled (ATD) was extended to the mentally ill. Over three years have elapsed since this program was transferred to the Social Security Administration and renamed Supplemental Security Income (SSI). Has a social, political, economic, and psychological phenomenon as important as this one received the scrutiny it deserves? The extension of eligibility for ATD, now SSI, to the mentally ill in 1963 had a major impact on psychiatry. What have been the benefits and what have been the adverse effects of this eligibility?

BENEFITS OF THE ATD TO SSI SHIFT

The beneficial consequences have been impressive. First and foremost, a source of funding became available that made it possible for the mentally ill who are unable to support themselves through work or private funds to move out of state hospitals and be maintained in the community. Previously, state governments had been willing to bear the cost of state hospitals, making only feeble and scattered attempts to provide funding for community alternatives. The frequently adverse consequences of prolonged state hospitalization were evident and were even made known to the public on occasion through newspaper exposés (1). However, the fear of the mentally ill and the public's apathy and desire to isolate them in locked and usually distant institutions prevailed. The advent of the phenothiazines and the community mental health movement made it more feasible for the mentally ill to live outside of the massive, impersonal institutions, but only the availability of ATD funds enabled resourceless persons, who had spent or would have been destined to spend many years in state hospitals, to be placed in a variety of community living arrangements. These ranged from good to poor, from independent living to board and care homes to convalescent hospitals. In some cases ATD payments made these patients more acceptable to their own families; before this financial support was made available the patients had sometimes been regarded primarily as an economic and emotional burden. Although there were many indignities to be suffered in the process of being approved for ATD, the end result was a dependable source of income for the mentally ill. We are convinced that many thousands of patients could have been discharged from state hospitals years earlier had ATD been available to them. Furthermore, the extension of welfare and income maintenance to the mentally ill meant that their needs were at last recognized; prior to this, ATD was available only for the physically disabled.

From the beginning, there were concerns about potential problems with this process, particularly in terms of officially labeling this group "totally disabled" and "mentally ill" and thereby stigmatizing them. Because of this, although the program was still called ATD, the abbreviation no longer stood for "Aid to the Totally Disabled" as it had initially but simply for "Aid to the Disabled." To indicate the possibility of recovery, a periodic review of eligibility was required by the regulations although it was usually performed only in a perfunctory way. While these changes were a step in the right direction, we think the term "disabled" was impressed on the minds of recipients, who generally continued to feel labeled and stigmatized.

The change to SSI, administered by the Social Security Administration, has had an important effect on delabeling and decreasing the stigma of ATD (2). A recent study (3) revealed a number of important effects of the shift from ATD to SSI. Most of the subjects in this study referred to themselves as being "on Social Security" or "on Social Security insurance," indicating a delabeling effect. Their financial support no longer clearly labeled them as psychiatrically disabled, and most no longer considered themselves to be on

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2-6, 1977.

welfare. The term Social Security had a more normative sound to the recipients. Thus, SSI has resolved or partially resolved some important problems of the mentally ill. But have new problems been created?

There has been a mass exodus from state hospitals, and tens of thousands of state hospital patients have been discharged. However, it has come to be recognized that an appreciable number of them are still not really integrated into community life (4). They live impoverished, inactive lives "in the community," and are open to exploitation by a variety of persons who take advantage of their helplessness (5). Community mental health professionals have by and large neglected them, preferring to focus on preventive programs and on treating attractive, verbal neurotics and individuals with character disorders. Recently, new interest has developed in treatment and rehabilitation programs for long-term, severely ill psychiatric patients. A component of such programs is usually social and vocational rehabilitation designed to enable these patients to "join in the mainstream of society" and experience the satisfactions of participation and even production.

SECONDARY GAIN IN SSI

To what extent does the aspect of secondary gain inherent in SSI interfere with such an approach? Although much has been written about compensation neurosis, it is noteworthy that little has been said publicly about the corresponding, although more subtle, problems inherent in the SSI program. Perhaps we do not mind paying for mental illness as long as it keeps the patients quiet and out of sight. It is the thrust of this article that serious consideration should be given to all aspects of the impact of SSI on the psychiatrically disabled. Let us turn first to problems of vocational rehabilitation.

An event in Missouri highlights the disincentive effects of SSI. When ATD was made readily available for psychiatric patients, one-third of those enrolled in sheltered workshops precipitously quit (Hilary Sandall, personal communication, May 1976). Unfortunately, no follow-up study was done and we do not know how these persons fared in the long run. However, this event made the problem clear. Large sums of money are being appropriated for vocational rehabilitation for the mentally ill, but at the same time there is undermining of their already weakened resolve to overcome their apprehension and try to deal with the everyday demands of life, such as self-support and achievement of a measure of independence.

Frequently, although by no means always, the severely mentally ill have a reduced work capacity. For many, the routine demands of work and social relations are major stresses. So much effort goes into their struggle with illness that they have little energy left to deal with a work situation. Handling interpersonal relationships with supervisors and coworkers is a major stress. The very thought of work [redacted] it carries the risk of yet another failure. [redacted] or at least protective work setting and an adequate preparatory period of vocational rehabilitation need to be made available for many of these precariously compensated people.

Those who believe in the value of vocational rehabilitation stress that heightened self-esteem issues from experiencing oneself as productive, as making a contribution to society, and as achieving at least partial self-support and independence. Work therapy is recognized as being fully as important as talking therapy. Having no reason to get up in the morning and no structured day to look forward to causes great voids in the lives of the severely mentally ill. Rewarding and gratifying use of leisure time is equally important. A combination of work and play is both normative and curative.

How does this square with a system in which continued financial support at a relatively low standard of living is contingent upon the client's maintaining a sick status? When one includes Medicaid, food stamps, the supplement to the basic federal grant supplied by a number of states, the exemption from taxes, and the possibility of pooling one's resources with another recipient, the standard of living may not be so low. It is not surprising that a large percentage of the mentally ill remain "disabled" and totally (or almost so) dependent on SSI. Most of these persons could be rehabilitated only into low-paying sheltered employment or low-level jobs even if they succeeded in overcoming their fear of venturing forth into the world of work. Moreover, they fear that such employment will result in a reduction of their already marginal standard of living and fear that they will lose one of the cornerstones of what little security they have, their SSI status (6). The secondary gain of illness, already a problem with many long-term psychiatric patients, is thus further reinforced.

Case Example

Mr. A, a 26-year-old man, has been hospitalized three times with a diagnosis of paranoid schizophrenia. His social worker suggested that he apply for SSI during his second hospitalization, and he has now been on SSI for 2 years. He had held a number of low-level jobs, but none for more than 6 months and none in the last 2 years. He is now seeing a psychiatrist and takes antipsychotic medication on a regular basis. He was referred to a vocational rehabilitation counselor who felt Mr. A could handle a low-pressure job, providing that he remained in treatment. The counselor arranged for him to be interviewed for a job as groundskeeper at a golf course. The foreman there handles his employees well and has supervised ex-mental patients in the past with good results. The prospect of being a groundskeeper appealed to Mr. A. He liked outdoor work, and the job would involve minimal demands to interact with other people. He found staying home all day difficult and depressing; time hung heavy on his hands. He did not know how to answer when people asked what he did. Mr. A was interviewed and hired, but later that day he called the boss and quit the job. Why? Later he talked with his counselor about his fear of failure.

Despite reassurance from both his counselor and the Social Security office, he could not be convinced that he would not permanently lose his SSI if he accepted the job; he remembered well the bureaucratic red tape and interminable delays involved in getting SSI initially and then again when he was discharged from the hospital and had to be reinstated. Besides, Mr. A told his counselor, his net pay from the job (at minimum wage) would be little more than his SSI check (which includes the California supplement) plus food stamps. He would be taking quite a chance, and he was frightened. At this writing, 2 years later, nothing has changed. Mr. A refuses to see his vocational counselor and is depressed and immobilized.

The message given to the patient by the SSI system is fully as important as the financial remuneration. Essentially, he is told "you are sick, disabled, and unable to work." Rehabilitation may be mentioned, but usually it does not come through to the patient with any real conviction.

The SSI system thus does not counteract the pull toward regression and dependency. Its purpose is income maintenance, not helping the person act or feel like a contributing or significant member of society. In terms of his source of income, the person perceives that society expects little of him. If the recipients of SSI choose to do so, they have the means to live an undemanding life with family or in a board and care home. There is little incentive to participate in a treatment program, either social or vocational. For a significant proportion of schizophrenic patients who have ego strength sufficient only to cope with minimal demands and social stimulation (7), this may be entirely appropriate. However, such a system undermines the already reduced motivation of many mental patients, both schizophrenic and nonschizophrenic, who could benefit from rehabilitation programs.

WHAT CAN BE DONE?

A first step would be to screen persons very carefully for entry into the SSI system and send them in this direction only if they are truly disabled. A major problem is the pressure from local jurisdictions, cities, and counties to divert persons from general relief or general assistance (funded entirely by local money) to SSI (funded primarily by federal and state money). Persons who may need general relief only for a limited time of crisis find themselves propelled into a system where, despite the perfunctory yearly SSI review, they may remain for years or for life. Sometimes the mere fact that a person is in psychotherapy seems sufficient to a welfare department eligibility worker to initiate an SSI application for that individual, even though he may have functioned well in the recent past and is only temporarily disabled. Such inappropriate entries into the SSI system need to be reevaluated, and primary consideration should be given to the long-range interests of the patient.

Another way to reduce the occurrence of chronic regression in the SSI system is to make yearly SSI reevaluations more meaningful. Currently they consist of an essentially mechanical financial eligibility check, with little concern for the patient's nonmonetary needs. Instead, each patient should be carefully evaluated by rehabilitation professionals who would offer the opportunity of social and vocational rehabilitation and explore its applicability to the specific person, with sensitive assessment of his capabilities and limitations. Patients who are not likely to withstand the stress of such activities should not be pressured or made to feel guilty about not participating in them. Further, the opportunity to receive rehabilitation should be seen both by the patient and the Social Security Administration as a benefit, like Medicaid, not as a requirement, and the patient's participation —or nonparticipation— in rehabilitation programs should in no way affect his eligibility for SSI.

To minimize the disincentive effects of SSI and the sick role, the law should be liberalized so that SSI recipients are allowed to keep a greater share of earnings from employment; under the current arrangement, any significant amount of earned income is deducted from their SSI checks.

At this time, we cannot predict which of our patients will benefit from a social integration program and which might react adversely to such efforts therefore, we suggest that every person at the point of application and approval of SSI be given every opportunity to participate in a comprehensive treatment and rehabilitation program. Whatever services are indicated should be made available: individual and group psychotherapy, social and vocational rehabilitation, training, sheltered work settings, employment assistance day treatment, linkage to therapeutic housing programs, and social services. Patients should be monitored to ascertain how they respond to treatment and to inducements to greater social and occupational participation. If clients react adversely, manifest a recrudescence of symptoms, or seem refractory to active help, the professional should at any point in the process be able to reset their goals and accept the clients limitations and possibly their need for a passive, dependent lifestyle that will make minimal demands on them. With this perspective, professionals will leave the door open to treatment and rehabilitation opportunities in the future. In the meantime, they will offer the patient those services that he can or will accept, including the option to call at times of crisis or great stress. Efforts must also be made to upgrade residential facilities and bring treatment and supportive services to patients who are not ready to come to them.

Finally, we advocate discussion and reassessment of the unintended adverse results of a social policy that was conceived in a humanitarian spirit and has brought about so many favorable developments for the mentally ill. The topic is often avoided because so many professionals fear that even the raising of questions will support the arguments of those extremists who would abolish social programs because they consider

any social dependency immoral, even that brought on by psychiatric disability.

The Mind-Body Dichotomy Reified: An Illustrative Case

BY MARK SCHOENBERG, M.D., MORTON G. MILLER, M.D., AND CONSTANCE E. SCHOENBERG

Cartesian dualism, the splitting of human existence into mind versus body, is at times reified with unfortunate consequences. The authors report a case in which a social policy formulation based on such diagnostic dualism resulted in the denial of health-related facility placement to a patient. They argue that this denial was prejudicial and illogical and that benefits should be related to a functional disability rather than to diagnosis.

THE CONCEPT of psychic dualism—of psyche as a separate entity from soma—has haunted psychiatry since its inception. We would like to report a case[1] that illustrates the reification of this concept in a matter of public policy and discuss the importance of such reification.

CASE REPORT

Mr. A was 38 years old when we saw him. He was born in New York State in 1938. He had a possible history of use of instrumentation at delivery. A diagnosis of mental deficiency as well as mucus colitis was reportedly made when he was 18 months old. At the time, he was known to bang his head. At the age of 3 he was brought to a major university teaching hospital and diagnosed as mentally deficient. Institutionalization was recommended when he was 4, and he was admitted to a private institution, where his IQ was found to be 47.

One year later he was transferred to a state facility with the diagnosis of mental deficiency, undifferentiated, imbecile; his IQ was 35. He was described as clean, tidy, and able to dress himself. He lived in a succession of state facilities for the mentally retarded until he was 21. At that time he was transferred to a state psychiatric hospital with auditory and visual hallucinations, hyperactivity, assaultive behavior supposedly in response to command hallucinations, and periods of withdrawal. A diagnosis of psychosis with mental deficiency was made, and treatment with neuroleptics was instituted. He was given phenytoin sodium (Dilantin) and phenobarbital for 3 years, although no specific mention was made of seizures. At the age of 30 he was said to be no longer psychotic. At the age of 33 he was discharged to a foster home and to outpatient clinic treatment. In 1975 his neuroleptics were stopped, and his psychotic symptoms did not recur.

The patient's family had no recorded history of mental retardation or major mental illness. Physical examination revealed that the patient was thin and had multiple burn scars from dropped cigarettes. There were no focal neurological findings, stigmata of chromosomal damage, or evidence of metabolic defect.

The mental status examination revealed that the patient was disoriented to time, place, and person. His speech was limited and concrete, and he had a markedly limited fund of knowledge. However, he could hold a coherent conversation on simple subjects. There were no Schneiderian first-rank symptoms, no hallucinations, no delusions, and no apoph-

anous phenomena. His affect was restricted, and his mood was apathetic.

While in the foster home Mr. A became increasingly confused and disorganized. He also started to have fecal and urinary incontinence. After a negative workup for organic causes, he was started on imipramine, 25 mg h.s., which improved but did not eliminate his enuresis.

After a home visit, a social worker judged the foster home unable to provide adequate supervision and a request was made for an application of transfer to a facility with both a health-related and a nursing home component. The request was based on the patient's continuing problems with hygiene and self-care, urinary and fecal incontinence, and worsening disorientation. The Department of Social Services denied a request for placement with the following note: "Deteriorating mental status does not justify Health-Related Facility status." Reevaluation was requested and disapproved on the basis of the following policy:

1. Placement of mental hygiene discharges in a . . . Health-Related Facility shall be prior approved by the local social services district Medical Director.
2. Patients with exclusively psychiatric diagnoses will not be approved for such long-term care.
3. A physical condition must exist which warrants care.
4. Not appropriate for . . . H.R.F. [health-related facility] because they [patients such as Mr. A] are primary [sic] mental patients. These facilities have no commitment to care for such patients, and there is no proof that they can take care of these patients.
5. We must assume priorities—physical vs. mental.

This decision was appealed. Several months later, the patient was admitted to a general hospital with stasis edema and cellulitis of the legs. He was then placed in a health-related facility on the basis of this physical condition. The appeal was denied on its merits.

DISCUSSION

Most of us speak and act as if our existence could be neatly divided into mind and body. We recognize that many schools of thought do not postulate a mind-body dichotomy, but we observe that most followers of these various schools usually behave in ways that imply or assume such a dichotomy. The field of psychiatry is polarized into psychodynamics against psychobiology. Psychology is polarized into humanists and social psychologists versus behaviorists, neuropsychologists, and psychobiologists. Psychiatric social work is usually identified with a psychic or mind position (attribution or labeling theory, psychological or social etiology theory). Caseworkers, however, are often relegated to a somatic position when their function is purely adjunctive to medical treatment. The lay public continues to stigmatize mental illness as different from and more shameful than physical illness. The legal profession, which is responsible for most of the policy making in our society, has been greatly influenced by Szasz, who, according to Roth (1), argues against the disease model of psychiatric illness by postulating a fixed mind-body split.

We would argue that the mind-body split is a false dichotomy. Human mental function, conscious and unconscious, is integrally connected with the function of the brain in the milieu of the body, and the integrity of brain and body is inextricably related to mental function. Evidence from the fields of genetics (2–4), neurophysiology (5), physiology (6, 7), and epidemiology (8, 9), as well as neurotransmitter hypotheses and stress-diathesis and multifactorial theories, all point to the influence of soma on psyche. Conversely, the elucidation of the function of the hypothalamic-pituitary axis, the theoretical basis of somatopsychic medicine, as well as specific works on life stress (10), psychosocial dwarfism (11), and emotional influences on physical disease (12), all point to the consequence of psyche and soma. It is also worth noting that *DSM-II* (13), the supposed basis for mental diagnosis, contains many conditions that are physically based, such as organic brain syndrome, psychoses associated with cerebral conditions, and psychophysiological reactions. It is on this basis that we reject the concept of a mind-body dichotomy.

The case presented is even more poignant because, even if we postulate a mind-body dichotomy, Mr. A most likely suffered from a physical illness. The severity of his illness, its early onset, the possible occurrence of seizures, his visual hallucinations, and his increasing disorientation all point to an organic syndrome. In addition, the patient's need for nursing care was due to his physical problems of incontinence and inability to take care of himself. For this reason, the denial of care on the ground that the patient had a mental condition strikes us as illogical and prejudicial.

Current proposals to accelerate community placement of individuals with mental retardation (the "Willowbrook Decree") and chronic mental illness will exacerbate the consequences of the inconsistency in current social policy formulations exemplified by the case of Mr. A. In our experience, individuals with a primary diagnosis of mental retardation with a history of even one psychotic episode and subsequent hospitalization in a state mental hospital are doubly stigmatized. Frequently rejected by community programs for mental retardation because of their history of mental illness, they are likewise often deemed not suitable for programs geared to the needs of individuals with functional psychoses.

Federal policy provides that services rendered under Medicaid should not discriminate by diagnosis. In the case cited, clinical facts were ignored in favor of a philosophical construct of mind-body dualism. The patient was penalized for his failure to fit neatly into a "clean" category. Continued deterioration of his mental status would almost certainly have resulted in his rehospitalization in a mental hospital. Although this result is clearly not consistent with the precept of least restrictive alternative, it looms frequently as the inevitable consequence of these dichotomous policies.

We would recommend that social policy reflect the unity of mind and body. "Mental" patients should not

be denied benefits available to patients with "physical" illness, and "organic" patients should not be excluded from the programs of psychosocial rehabilitation available to "mental" patients. As a matter of social policy, programs and benefits should be geared to patients' functional disabilities—not to their diagnoses.

CLINICAL AND RESEARCH REPORTS

This section contains 1) new research findings, including preliminary data from pilot studies, either clinical or laboratory; 2) worthwhile replication studies; 3) case reports that describe a truly new syndrome or cast new light on established ones; and 4) case reports that indicate a new therapeutic procedure of potential value or call attention to adverse effects of drugs or previously unreported complications of therapeutic interventions. Program descriptions and literature reviews cannot be printed in this section. Criteria for format are listed in "Information for Contributors" in each issue; papers that do not adhere to these criteria will be returned to the author.

Mental Disturbances During Bromocriptine and Lergotrile Treatment of Parkinson's Disease

BY MICHAEL SERBY, M.D., BURTON ANGRIST, M.D., AND ABRAHAM LIEBERMAN, M.D.

In recent years there has been increasing support for the hypothesized role of dopaminergic hyperactivity in schizophrenia (1). Schizophreniform psychoses characterized by paranoid ideation, delusions, inappropriate behavior, and, in some cases, hallucinations and disorders of thinking and affect have been observed after the administration of a variety of drugs that have a common denominator of dopaminergic facilitation (2). Organic confusional syndromes characterized by temporal and spatial disorientation, agitation, and delirium have also been observed (3, 4).

Bromocriptine and lergotrile are newly developed dopamine agonists that have shown promise in the treatment of Parkinson's disease (5–7). Early clinical trials demonstrated mental disturbances as a side effect of both of these drugs (5–9). In view of this we thought it would be of interest to report our recent experience with a larger series of parkinsonian patients treated with these agents.

Method

Between 1974 and 1977, 81 patients with advanced Parkinson's disease who gave written informed consent were treated with either bromocriptine or lergotrile (7, 8). Some received trials of both agents; 66 were treated with bromocriptine (mean dose=33±2.6 mg) and 53 received lergotrile (mean dose=39±3.1 mg). Bromocriptine or lergotrile was added to each patient's regimen at an initial dose of 5–10 mg/day. The daily dose was increased by 5–10 mg each day. During the course of the study, increased abnormal involuntary movements (AIMs) made it necessary to reduce the dose of L-dopa by 10% in both drug groups. The dosages of amantadine and/or anticholinergics were kept constant throughout the study.

Patients with moderate or marked organic mental syndromes were excluded. Patients with mild organic mental syndromes or histories of depression or psychotic behavior were included if their psychiatric condition was stable. All such patients underwent an EEG and a psychiatric evaluation before they were committed to the study.

Among the 66 patients treated with bromocriptine 17 developed mental changes. In 14 patients the mental changes necessitated discontinuation of the drug; in 5 cases the changes were severe enough to require additional psychiatric consultation. In 3 of the 17 patients the mental changes were transient and disappeared when the dose of bromocriptine was reduced. Nine of the 17 patients had exhibited similar changes on L-dopa. Among the 53 patients treated with lergotrile, 13 developed mental changes. In 12 patients the mental changes necessitated discontinuation of the drug, and additional psychiatric consultation was required in 5 cases. In 2 of the 14 patients, the mental changes were transient. Eight had exhibited similar changes on L-dopa. The 10 patients with severe mental changes on bromocriptine or lergotrile form the basis of this report. Statistical analyses were performed using Student's one-tailed t test at the 95% confidence level.

Results

Comparative data on the 10 patients whose mental changes on bromocriptine or lergotrile were severe enough to require additional psychiatric consultation

*OCS=organic confusional syndrome, SP=schizophreniform psychosis. All schizophreniform psychoses occurred in a clear sensorium.

are summarized in table 1. Further clinical details of drug response patterns are available from the authors on request.

Among these 10 patients, 3 developed an organic confusional syndrome and 4 showed a schizophreniform psychosis consisting of paranoid ideation, delusions, and hallucinations in a clear sensorium. One patient showed mental changes with characteristics of both syndromes. In this patient the organic confusional features were mild, and paranoid features (delusions of being poisoned, filmed, and tape-recorded) dominated the clinical picture. The remaining 2 patients showed more subtle changes in behavior and personality without confusion that were noted by families but not by the hospital staff.

The mean age (±SEM) of the 3 patients exhibiting the organic confusional syndrome was 72.3±0.3 and that of the 6 patients with nonconfusional syndromes was 61.6±3.3, a significant difference. In addition, 2 of the 3 patients who developed mental changes in a clouded sensorium had moderately abnormal pretreatment EEGs consisting of frequent 3–7 Hz slow waves bilaterally. In contrast, only 1 of the 6 patients who developed mental changes in a clear sensorium showed an EEG abnormality, and this was only minimal, consisting of 5–7 Hz slow waves accentuated over the left temporal region. The patient who showed both mild confusional and florid paranoid symptoms had a minimally abnormal EEG, with infrequent 5–7 Hz slow waves bilaterally.

There was no correlation between the type of mental disturbance and the duration or severity of parkinsonism, the duration of treatment with L-dopa, or the development of abnormal involuntary movement on L-dopa. One of the patients who developed an organic confusional syndrome on bromocriptine had a mild organic mental syndrome before treatment was initiated, and 2 of the patients who developed schizophreniform psychoses had previously exhibited depression sufficiently severe to require psychiatric intervention but not hospitalization.

Discussion

In this group of patients there was a relationship between antecedent organic mental changes and the development of organic confusional syndromes on lergotrile or bromocriptine. Not only was the group with the organic confusional syndromes older, but 2 of these 3 patients had a mild organic syndrome before they were given bromocriptine or lergotrile. Two of these patients also had moderately abnormal EEGs before they were given the drugs. This finding of an increased incidence of organic confusional syndrome in patients with an underlying dementia is consistent with previous observations. In 1971, Goodwin and associates (3) reviewed all the published studies on L-dopa in Parkinson's disease in which the nature of psychiatric side effects was specified (predominantly patients without dementia) and found confusion or delirium reported in 35 of 1,045 patients (3.35%). In contrast, Sachs and associates (10) administered L-dopa to 15 parkinsonian patients with specifically documented severe dementia, and all developed organic confusional syndromes.

Although our 10 patients were receiving drugs other than bromocriptine and lergotrile, the temporal relationships between bromocriptine or lergotrile administration and the emergence of symptoms suggest that these drugs were responsible. This impression is supported by the fact that such reactions were noted in

previous studies with these drugs (5–9) and by the known capacity of a variety of other dopaminergic agonists to induce similar psychiatric disturbances.

Thus, two main conclusions emerge from these observations. First, lergotrile and bromocriptine, like other drugs that facilitate dopaminergic activity, can in some patients act as specific psychotomimetic agents producing paranoid schizophreniform psychoses. This particular finding constitutes additional support for the hypothesized role of dopaminergic overactivity in schizophrenia. Second, these drugs, like many other agents, can also produce in some patients a nonspecific organic confusional syndrome, with age and preexisting dementia as predisposing factors.

Tardive Dyskinesia Reinduced by Lithium Carbonate

BY BERNARD D. BEITMAN, M.D.

Reports concerning the short-term effect of lithium salts on the symptoms of tardive dyskinesia include a number of apparently contradictory findings. In studies of 6 and 15 patients, respectively, Reda and associates (1) and Gerlach and associates (2) found mild improvement in dyskinetic movements. However, in two separate studies of 10 patients each, Simpson and associates (3) found no significant change. In a single case report Crews and Carpenter (4) described an aggravation of tardive dyskinesia at toxic doses of lithium, whereas Gerlach and associates (2) reported complete remission of dyskinetic movements in a patient at toxic doses of lithium.

These studies have involved interaction of lithium and tardive dyskinesia over periods of 12 weeks or less. The following case report suggests that lithium may reinduce a dyskinesia that has been quiescent for many years.

Case Report

The patient, a 56-year-old woman, had had recurrent depressive episodes since 1960. These episodes were characterized by dysphoric mood, lack of energy, 3–4 hours of sleep each night with early morning awakening, decreased appetite, and weight loss. She was treated with most of the tricyclic antidepressants, numerous courses of ECT, neuroleptics, monoamine oxidase inhibitors, and minor anxiety agents. Only short courses of ECT were consistently effective. However, the patient became afraid of possible organic impairment resulting from ECT. After reading about the effectiveness of lithium in certain types of depression she came to the psychiatric medication clinic at the University of Washington seeking a lithium trial.

Of note in her medication history is the fact that she took thioridazine, 25 mg b.i.d., from January 1967 to March 1973. She discontinued the medication because she began to develop facial contortions: "My mouth was moving. All the time grimacing, my lips moved a lot, and I couldn't sit with a composed expression on my face." Within 2 weeks after she stopped taking the thioridazine, the oral-facial dyskinesia ceased.

The patient was stabilized on lithium carbonate during December 1975 at a dose of 300 mg t.i.d. with a serum lithium level of 0.9 mEq/liter and experienced no recurrence of depression when she was taking the drug. She decided to stop taking lithium in March 1977 "to see if it was the lithium or my belief in it." Within a week she began to redevelop symptoms of depression. After a few weeks of increasing discomfort she resumed the lithium and regained her normal mood. In June 1977 she began to experience a mild oral dyskinesia that seemed to her very similar to the dyskinesia associated with thioridazine. Her neurologist reported "occasional grimacing and spontaneous facial movements which increased when specific tasks involving the extremities were requested." The patient described a feeling that her "lip-

weren't right, they were tight," in addition to the uncontrollable grimacing.

During a short trial of trihexyphenidyl the dyskinesia ceased immediately; later, it returned when the anticholinergic was discontinued. After being stabilized on 2 mg of trihexyphenidyl t.i.d. for 3 months, she experienced a mild recurrence of symptoms. In order to test the effects of the medications on her dyskinesia within the limits she would tolerate, she was asked to stop taking the trihexyphenidyl for 2 days and then to discontinue the lithium for 4 days. Without the anticholinergic, the dyskinetic movements worsened, and when both drugs were discontinued, they worsened further. On resumption of both medications, the dyskinesia was much reduced but still present. The most effective course of treatment has yet to be defined.

Discussion

The physical signs of the movement disorder, its time of appearance, and the exacerbation of dyskinetic movements on withdrawal of the implicated medication are characteristics of neuroleptic-induced tardive dyskinesia. Two interrelated explanations may be offered for the role of lithium in this case. First, lithium may simply unmask certain pathological conditions (5), suggesting that the previous neuroleptic administration had created an abnormal neurochemical substrate on which the lithium acted to cause the clinical picture. Second, lithium salts may reduce dopamine activity in a manner parallel to but weaker than the neuroleptics. For example, lithium may accelerate the reuptake of dopamine by synaptosomes, thereby reducing the total amount of dopamine (6). This neuroleptic-like activity of lithium might explain the short-term amelioration of tardive dyskinesia by lithium (1, 2) as well as the appearance of dyskinetic movements later in lithium therapy, as occurred in the case reported here. There have been no reports of lithium alone being associated with the appearance of tardive dyskinesia, so the best explanation may be a weak neuroleptic-like activity combined with a preexisting pathological substrate.

In reviewing this case report one must also consider the possibility that the dyskinetic movements might have recurred without the influence of lithium carbonate. Unfortunately, too little is known about the natural history of those tardive dyskinesias which remit on withdrawal of the offending medication. The temporal association of lithium with the reappearance of the dyskinetic movements suggests a causal connection. This connection implies that lithium, like neuroleptics, might have to be discontinued to prevent the dyskinesia from becoming chronic.

It should be noted that trihexyphenidyl was used instead of, for example, deanol because evidence is mounting that there are at least two pharmacologically distinct subtypes of tardive dyskinesia. In one type there may be a relative dopamine excess, while in the other there may be a relative cholinergic excess (7). The existence of multiple pharmacologic subtypes may also explain the reported variety of responses to lithium salts. At present, the only way to differentiate the subtypes is through pharmacologic trials with potentially helpful medications, including deanol and the anticholinergics.

Successful Treatment of Thalamic Pain with Apomorphine

BY DENNIS P. MILEY, M.D., ALAN A. ABRAMS, M.D., J. HAMPTON ATKINSON, M.D., AND DAVID S. JANOWSKY, M.D.

Evidence exists suggesting a role for a catecholamine neurotransmitter, dopamine, as a moderator of analgesia and pain perception. L-Dopa, a dopamine precursor, elevates pain thresholds (1), and amphetamine, an indirect dopamine agonist, increases morphine analgesia (2). Also, in animal models, opiates stimulate dopamine biosynthesis (3). Apomorphine, a ligand for dopamine receptors, is structurally related to dopamine and acts directly as a dopamine receptor agonist (4, 5). Based on the hypothesis that apomorphine might have analgesic properties, we tested the effect of apomorphine on thalamic pain.

The authors are with the Department of Psychiatry, University of California, San Diego, School of Medicine, La Jolla, Calif. 92037, where Dr. Miley is Fellow in Consultation-Liaison, Dr. Abrams is Resident, Dr. Atkinson is Assistant Professor, and Dr. Janowsky is Professor. Case Reports

Case 1. A 24-year-old man with dystonia musculorum deformans was hospitalized because of intractable pain. Two bilateral cryothalamectomies (2 and 3 years previously) ameliorated the patient's movement disorder, but a severe left-sided dysesthesia developed after surgery. Over a 2-year period, attempts to achieve analgesia with opiates, anticonvulsants, neuroleptics, and tricyclic antidepressants were unsuccessful, as was implantation of a dorsal column nerve stimulator.

At the time of his admission, the patient was bedridden, complaining of excruciating left-sided pain. Mild dysarthria, spasmodic torticollis, myoclonus, and severe left arm flexor spasm were present. Sensory examination demonstrated increased threshold to vibration, pinprick, and touch, as well as dysesthesia in the left arm. EEG findings were unremarkable. The patient's pain was refractory to intramuscular meperidine in a dosage of 200 mg every 3 hours.

Meperidine detoxification was accomplished by methadone substitution and withdrawal, and the patient was sedated with chlorpromazine. Thalamic pain syndrome was independently diagnosed by the neurology service on the basis of sensory loss associated with hyperpathia, intractable pain, and movement disorder.

Sequential drug trials were initiated for pain management. Drug trials were evaluated by 1) pain estimate and visual analogue scores as described by Sternbach (6), 2) behavioral observations recorded daily by both nursing and physician staff, 3) the McGill-Melzack Pain Questionnaire, and 4) the Profile of Mood States (POMS), all administered three times weekly.

Chlorimipramine, 5 mg/kg p.o. for 2 weeks, led to an intensification of pain complaints, deterioration in mood, manifest agitation, and a fourfold increase in chlorpromazine requirements from 300 to 1200 mg p.o. q.d. Therefore, chlorimipramine was discontinued and amitriptyline and chlorprothixene were started. Shortly thereafter, the patient had a left aversive seizure. An EEG demonstrated an irritative right anterior and parasaggital focus, so diphenylhydantoin was started. His severe, constant pain was unabated so amitriptyline and chlorprothixene were stopped after 10 days. Transcutaneous nerve stimulation afforded no relief.

Treatment with up to 5 mg/kg p.o. q.d. of apomorphine for 10 days resulted in a decrease of approximately 40% in pain estimate and visual analogue scores over baseline (from a weekly average score of 80/100 to 45/100), associated with enhancement of vigor (POMS vigor raw score increased from a pretreatment score 10 to 17 on apomorphine, and the T score increased from 48 to 59, $p<.01$ for both comparisons). There was also some alleviation of depressed mood: the POMS depression raw score decreased from a pretreatment score of 20 to 12, and the T score decreased from 49 to 43 (p=n.s.). The patient's chlorpromazine requirement decreased to 200 mg q.h.s., given for sedation. By the end of the 10-day study period, the patient could function independently, walk with a cane, and actively participate in recreational and physical therapy. As his pain complaints diminished, his self-care and interpersonal relationships improved. Apomorphine-induced pain reduction was not reversed by naloxone, 0.2 mg I.V.

Case 2. A 55-year-old woman was transferred from another hospital for treatment of thalamic pain secondary to a right cerebrovascular accident suffered 4 months previously. Drug trials (carbamazepine, pentazocine, and diphenylhydantoin) and transcutaneous nerve stimulation had failed to moderate the patient's pain. Her medications at the time of transfer included flurazepam, diazepam, pentazocine, phenobarbital, and diphenylhydantoin.

The patient complained frequently of intense pain and exhibited extreme lability of mood. Left-sided hemianopsia and palsies of cranial nerves 7, 11, and 12 were present. Hemiplegia, hyperreflexia, ankle clonus, and a flexor plantar response were also present on the left. Appreciation of all sensory modalities on the left was profoundly diminished, with hyperpathia to light touch and cold.

Analgesic and psychoactive medications were stopped. She had had cortical seizures in the interval since the cerebrovascular accident, so the anticonvulsants were continued. An EEG demonstrated right hemispheric grade 2 dysrhythmia. A trial of chlorpromazine treatment for her thalamic pain was aborted because of severe anticholinergic side effects. Subsequently, the patient had another seizure, so carbamazepine was restarted and diphenylhydantoin was discontinued because of subtherapeutic serum levels.

Apomorphine, 0.5 mg subcutaneously every 6 hours for 3 days, was given in a double-blind, crossover design. When compared with placebo (subcutaneous saline solution) apomorphine resulted in resolution of spontaneous pain complaints, reduction in subjective estimates of pain intensity and frequency, a predominance of pain-free intervals, and increased tolerance for physical therapy. Cognitive deficits precluded quantification of pain rating and mood state.

Discussion

Conventional analgesic treatment routinely fails in the management of thalamic pain. Phenothiazines may afford some relief (7) and diphenylhydantoin is sporadically effective (8). Stereotaxic thalamotomy is of benefit, but in the majority of cases pain recurs (9). In the patients we have described, despite pharmacologic management (including phenothiazines and diphenylhydantoin) and prior neurosurgical intervention in the first case, sustained analgesia was not achieved before or during hospitalization until apomorphine was added to the treatment.

Apomorphine has been used medically for its central emetic effect. Advantage has also been taken of the drug's dopaminergic potentiation in the treatment of Parkinson's disease (10) and neuroleptic-induced movement disorders. Although it is a morphine derivative, apomorphine lacks intrinsic narcotic analgesic effects. Autoinhibition and reversible azotemia at high doses limit the clinical use of apomorphine (10); however, neither of these side effects was observed in these cases.

Although it is possible that drug interactions with apomorphine resulted in analgesia or that changes in mood may have altered pain tolerance, we believe that apomorphine was helpful in controlling these patients' chronic pain. Since the pain was unresponsive to multiple treatment modalities, it is unlikely that the apomorphine effect was a placebo response. Further studies of apomorphine's usefulness in the treatment of thalamic pain are in progress.

Intravenous Diazepam in the Treatment of Neuroleptic-Induced Acute Dystonia and Akathisia

BY DINSHAH GAGRAT, M.D., JAMES HAMILTON, M.D., AND ROBERT H. BELMAKER, M.D.

Dystonia and akathisia are two major extrapyramidal side effects of neuroleptic treatment. Dystonia, characterized by acute spasm of a muscle group, usually occurs during the first few days of neuroleptic treatment. Although it may remit spontaneously, dystonia is considered a medical emergency, and treatment with intravenous diphenhydramine is usually recommended (1). A major danger of diphenhydramine treatment is urinary retention or exacerbation of glaucoma or cardiac arrhythmias in predisposed patients (1).

Akathisia is an inner feeling of restlessness that may be accompanied by pacing and inability to sit still. It usually develops after weeks of neuroleptic treatment but is often seen earlier with the more modern high-dosage or parenteral neuroleptics. Standard treatment has been to administer anticholinergics orally, which does not take into account the often acute nature of akathisic restlessness. In addition, anticholinergics are often only partially effective in this syndrome (1) and carry the risk of the side effects mentioned above.

Diazepam has been anecdotally reported to be effective in neuroleptic-induced dystonia and akathisia (2–6). However, controlled study is necessary because these syndromes are often self-limiting or responsive to suggestion. Recent knowledge of the interactions of dopamine, acetylcholine, and GABA in the basal ganglia (7) make it seem logical that a GABA agonist like diazepam (8) might be equivalent to an anticholinergic in the alleviation of syndromes that result from dopamine receptor blockade. We therefore performed a double-blind trial of intravenous diazepam versus intravenous diphenhydramine in the treatment of acute neuroleptic-induced dystonia and akathisia.

Method

Subjects were selected from patients who developed acute dystonia or acute akathisia requiring immediate (intravenous) relief. Patients were excluded from the study if they were already on anticholinergic or benzodiazepine medication or had serious physical illness, especially glaucoma, prostatic hypertrophy, or cardiac or pulmonary disease.

Subjects were rated on a 4-point scale for dystonia or akathisia before the intravenous treatment and then 5 minutes, 15 minutes, 30 minutes, and 120 minutes afterward. The scale was defined as follows: 0=no dystonic or akathisic symptoms, 1=subjective feeling of muscle tightness or desire to contort (dystonia) or subjective inner restlessness (akathisia), 2=objective muscle spasm (dystonia) or objective restlessness (akathisia), and 3=severe objective muscle spasm (dystonia) or severe objective restlessness (akathisia). Solutions of diazepam (5 mg) or diphenhydramine (50 mg) were given slowly over 1 minute in syringes covered to conceal the different colors. Syringes were prepared according to a prearranged random order by one of us (R.H.B.) and administered by another author (D.G.), who was blind to the nature of the solution and who made the clinical rating observations. In addition to the symptom ratings noted above, D.G. rated drowsiness (absent, mild, severe) at each time point. After acute intravenous treatment the patient was usually started on oral anticholinergic medication for one to two weeks as clinically indicated according to the recommendations of Bassuk and Schoonover (1). Patients became eligible for re-study if the symptom re-

TABLE 1
Effects of Diphenhydramine and Diazepam on Akathisia and Dystonia Severity Ratings

Symptom and Treatment	Number of Treatments	Mean Severity Rating*				
		Baseline	5 Minutes	15 Minutes	30 Minutes	120 Minutes
Dystonia						
Diphenhydramine	10	2.7	.70*	0.00	0.00	0.00
Diazepam	10	2.5	.70*	0.10	0.10	0.10
Akathisia						
Diphenhydramine	11	2.36	1.09*	0.82	0.55	0.64
Diazepam	9	2.22	1.44*	1.11	0.89	0.56

*All values for posttreatment severity ratings represent significant improvements over baseline ratings ($p<.01$, paired t tests).

turned after cessation of anticholinergics or if they had been treated for dystonia but later developed akathisia. Some patients were studied during more than one admission. Thus, a total of 40 intravenous treatments were given to 27 patients. Of these 27 patients who developed neuroleptic side effects and satisfied the other criteria for conclusion in the study, 26 were treated with haloperidol. This figure represents 30.6% of the patients treated with haloperidol in our unit over the period of study.

Results

Table 1 shows the effect of intravenous diazepam and diphenhydramine on the mean severity ratings of dystonic or akathisic symptoms. Both treatments are effective in both syndromes, with a significant reduction in symptom scale scores by 5 minutes posttreatment ($p<.01$, paired t test) that continued through 120 minutes. There were no significant differences in effectiveness between the two treatments at any time point. Drowsiness rating scores did not significantly differentiate between the two treatments (data not shown), although there was a trend for diazepam-treated patients to be drowsier.

Discussion

The present study suggests that intravenous diazepam is as effective as a standard anticholinergic drug in the treatment of acute neuroleptic-induced dystonia and akathisia. Three factors have made these neuroleptic side effects increasingly important: 1) increasing use of high-potency neuroleptics with considerable potential for inducing extrapyramidal disorders, 2) the spread of rapid tranquilizing techniques, which involve parenteral administration and rapid dosage increments, and 3) the realization that prophylactic use of anticholinergics may interfere with the efficacy of neuroleptic therapy (9) or cause another set of unwanted side effects. Safe and rapid treatment of extrapyramidal disorders has thus become increasingly important, especially for dystonias and akathisias, which are frightening to patients and may affect their future compliance with neuroleptic treatment (10). Diazepam seems to be an effective treatment for these syndromes and has the advantage of being familiar to psychiatric personnel, perhaps more so than diphenhydramine, and of being safe for patients with glaucoma or prostatic hypertrophy. Low doses of intravenous diazepam are sufficient, although the drug should be given slowly over the course of 1 minute to avoid danger of apnea. Although we did not see any instances of apnea with this low dosage, and apnea is very rare in patients who are not receiving other sedatives, clinicians should be aware of this possible risk when administering intravenous diazepam to patients with pulmonary disease, alcohol intoxication, or multiple sedative treatment.

Our study does not provide data on the use of diazepam orally over days or weeks in the follow-up treatment of patients with dystonia. For example, a patient with complicating severe prostatic hypertrophy would require follow-up treatment with diazepam because diphenhydramine and anticholinergics would be contraindicated. Our clinical experience suggests that it may be effective. Diazepam does not seem to act merely as a sedative in akathisia or as a muscle relaxant in dystonia as we have also seen cases of severe neuroleptic-induced akinesia, approaching stupor, that have responded to intravenous diazepam. Recent data on the interaction of diazepam with GABA in the brain suggest that the mechanism of action may be specific and central (8) and that diazepam may have interesting and important interactions with the neuropharmacology of schizophrenia.

Hyperthermia Associated with Chlorpromazine and Full-Sheet Restraint

BY PHILIP GREENLAND, M.D., AND WILLIAM H. SOUTHWICK, M.D.

Disturbances of thermoregulation are well-recognized side effects of phenothiazine tranquilizers and constitute some of the most serious reactions to these drugs. There have been reports of both hypothermia (1), especially in elderly patients during winter months, and hyperthermia (2), generally associated with high ambient temperatures and/or excessive physical activity. A number of reports of fatal heat stroke in association with phenothiazine emphasize the clinical significance of these thermoregulatory abnormalities (3).

We report here the case of a patient in whom the use of full-sheet restraint led to profound hyperpyrexia. Chlorpromazine appeared to be the only drug the patient had received that had the potential for harmful effects on thermoregulation. To our knowledge, this association has not previously been recorded in humans.

Case Report

The patient, an 18-year-old man, was admitted to the psychiatry service of Strong Memorial Hospital because of acute agitation and combative behavior. He had been in excellent health until he became depressed, withdrawn, confused, and irritable 2 weeks before his admission. Five days before admission, he developed a blank stare and delusional, paranoid thinking. He also expressed considerable guilt about recent frequent marijuana use. He did not use any other licit or illicit drugs, including alcohol. On the day of admission he became quite agitated and combative and was brought to the emergency room by his family.

The family history was remarkable in that his father had died suddenly of a myocardial infarction almost exactly 2 years before the patient's admission. His medical and psychiatric history was negative and he had no known allergies.

The initial diagnosis was schizophrenia, paranoid type. The patient was given chlorpromazine, 400 mg/day, which was gradually increased over 7 days to 2000 mg/day. He was intermittently secluded during this time because of combative behavior, but no other drugs were used and he was not restrained. A complete physical examination could not be done during this time, but vital signs, including temperature, were consistently normal.

On the 6th day of his hospitalization a full-sheet restraint was ordered because of severe agitation and self-destructive behavior, most notably tongue biting and flinging his body against the walls of his room. The Posey "restraint net," made of heavy nylon mesh, exposed only the head, arms, and lower legs. He remained agitated and thrashed about despite the restraint. Five hours later, the patient was diaphoretic, and his axillary temperature was 104.6°F. He had received one 10-mg dose of haloperidol I.M. approximately 20 minutes before the fever was recorded. He was on no anticholinergics and ambient room temperature was 70°F.

An examination was remarkable only for the fever and diaphoresis in addition to continued agitation. He was placed in a cool bath and his temperature rapidly returned to normal. Cultures of urine, blood, and sputum were all negative; his white cell count was 10,000 with a normal differential; and a chest X ray obtained the next morning was normal. His T_4 was also normal.

The next morning he was again put in restraints as a precautionary measure, but he was not at all active and vital signs were normal. A complete physical examination was unremarkable. He remained afebrile and calm, and the restraints were removed until approximately 6:00 p.m. when he became agitated and was again placed in full-sheet restraint. At 8:00 p.m. his axillary temperature was 105.0°F. He was subsequently given 5 mg of haloperidol I.M., but he had not received the drug previously that day. Physical examination and all laboratory measures were unchanged, and a cool water bath again led to rapid resolution of his hyperpyrexia.

Throughout the remainder of his hospitalization the patient received no additional phenothiazines, and his agitation and psychotic behavior were well controlled on haloperidol and benztropine mesylate. Restraints were no longer required, and fever did not recur.

He was discharged after 49 days of hospitalization with the diagnosis of acute schizophrenic episode and possible schizophrenia, paranoid type. He has remained well during 3 months of follow-up on low doses of haloperidol.

Discussion

Thermoregulation in humans is thought to involve a complex interaction between central and peripheral regulatory mechanisms. Central mechanisms probably occur in the caudal hypothalamus (4) and are mediated by both dopaminergic and serotonergic receptors (5). Peripheral mechanisms include vasoconstriction and dilatation, piloerection, and sweating, leading to increased or decreased heat loss by convection, radiation, or evaporation (4). Hyperthermia occurs when heat production exceeds heat loss by these various mechanisms (4).

A number of drugs are known to disturb these thermoregulatory mechanisms (6–8). The phenothiazines may affect thermoregulation by both central and peripheral mechanisms, although the impairment of hypothalamic thermoregulation is probably the major pathogenic mechanism (5). Severe hypothermia and fatal episodes of hyperthermia have been recorded in patients treated with phenothiazine. The hyperthermia is invariably associated with elevated ambient temperatures and/or excessive physical activity in humid en-

vironments (2, 8). The risk of hyperthermia with phenothiazines is increased when phenothiazines are given in combination with anticholinergics, which impair sweating and thus abolish a potent mechanism of heat loss (9).

The patient we have described demonstrated profound hyperpyrexia on two occasions shortly after he was placed in full-sheet restraint. On one occasion, after 7 days of high-dose chlorpromazine therapy a single intramuscular injection of haloperidol was given 20 minutes before the fever was recorded. The second febrile episode occurred when the patient was receiving chlorpromazine but no other medications. It would thus appear most likely that chlorpromazine was the drug involved, although haloperidol has also been known to produce thermoregulatory impairment (5). The significant and previously unreported feature of this case is the association of fever with restraint in a patient treated with a phenothiazine. The presumed mechanism of fever was a chlorpromazine-induced abnormality of central thermoregulation, combined with the inability to evaporate sweat due to the heavy nylon restraint, a situation analogous to that of a patient who is receiving both chlorpromazine and an anticholinergic. The agitated behavior appeared necessary for increased heat production since fever did not occurr in its absence, even when the patient was in restraint. That the stress of restraint in patients taking phenothiazines may lead to hyperthermia via central mechanisms alone has been suggested by experimental study of rabbits treated with apomorphine (10). However, full-body restraint did not produce hyperthermia in these animals, probably because it was also associated with sedation, which precluded excessive heat production. Hyperthermia did occur when these rabbits were put in neck restraints; those restraints were associated with aggressive behavior and therefore also increased heat production.

This case illustrates yet another potentially significant clinical situation in which hyperthermia may occur in association with phenothiazine therapy. Judiciousness in the use of full-sheet restraint in the agitated patient can now be added to avoidance of elevated ambient temperatures and cautious use of anticholinergics in patients receiving acute or chronic phenothizaine therapy. Recognition of this complication will expedite proper management and avoid inappropriate treatment of fever of obscure origin.

A Single-Blind Study of ECT in Patients with Tardive Dyskinesia

BY GREGORY M. ASNIS, M.D., AND MICHAEL A. LEOPOLD, M.D.

Tardive dyskinesia is a neurologic disease caused by neuroleptic medication. The syndrome usually consists of mild involuntary movements (1, 2) but occasionally becomes medically disabling, causing dysarthria, dyspnea, cyanosis, or dysphagia (3).

Most authors agree that when patients develop tardive dyskinesia, the dose of antipsychotic medication should be lowered or discontinued as the patient's mental condition permits in an attempt to reverse the disease process and to avoid possible complications (4, 5). A problem arises, however, when a patient with tardive dyskinesia becomes acutely psychotic. When one treats such patients with neuroleptic medication he is using the agent that caused the patient's iatrogenic disorder, which may increase the likelihood of an irreversible disease.

The use of ECT in tardive dyskinesia patients who are psychotic is now being considered. However ECT's effects on the dyskinetic process are unclear. One early report suggested that tardive dyskinesia had resulted from ECT for 4 of 33 tardive dyskinesia patients assessed (6), which raises the possibility that

ECT worsens tardive dyskinesia. However, recent reports of the beneficial effects of ECT on Parkinson's disease (7, 8), another extrapyramidal syndrome, raise the possibility of improving tardive dyskinesia symptoms by treating the psychosis with ECT.

This study was undertaken to evaluate the effects of ECT on the acutely psychotic patient with tardive dyskinesia.

Subjects and Method

Four women with tardive dyskinesia were admitted to an acute hospital ward because of psychotic decompensation. All patients had an oral-facial and limb dyskinesia that was first noted in the previous 6 months. Their prior neuroleptic use ranged from 2 to 8 years, with a mean of 3.5 years; their ages ranged from 43 to 69 years, with a mean of 56 years. All medications were discontinued 3 weeks before commencing ECT. If medication was absolutely necessary during the study, a minor tranquilizer was given.

Patients gave informed consent for the treatment and evaluation procedures. Bilateral ECT was given, preceded by intravenous sodium methohexital and succinylcholine HCl. Treatments were given three times a week. The total number of treatments ranged from 6 to 13.

Each patient's oral-facial dyskinesia was evaluated by the frequency count method of Kazamatsuri and associates (9). Patients were videotaped in a room alone for a 3-minute period. Every movement in the oral-facial region, such as tongue protrusion, lateral movement of the jaw, or lip smacking, was counted, and the number of movements per minute was obtained. Assessments were made at least twice during the baseline period, after every other ECT treatment (on the day of the treatment), and at 1 week and 2 months postECT. Recordings were made at the same time of the day and in the same setting. The movement frequency counts were done blindly from the videotapes by one of us (M.A.L.); tapes were shown in order. A 25% change in either direction was considered to be within the normal day-to-day variation and thus was considered as no change.

Results

As can be seen from table 1, the average oral frequency count of four patients did not change significantly during and after ECT from the initial baseline measurements. Patient 4 was the only one who showed a significant change during ECT (−27%) and after ECT (+50%). This patient had fluctuating pre-ECT baseline recordings varying as much as threefold, whereas the other patients' baseline recordings fluctuated only ± 20%.

At no time during or after ECT did a new area of the body develop a dyskinetic process, and no preexiotomy dyskinetic symptom disappeared.

Initially, all four patients benefited from a course of ECT and were discharged from the hospital. Patient 1 (manic-depressive illness, depressive type) after an initial 2-month follow-up was successfully treated with 1–2 ECTs every month for a total of 6 months. Patient 2 (schizo-affective schizophrenia, depressed type) was treated successfully with minor tranquilizers for an additional 6 months. Patient 3 (organic brain syndrome) and patient 4 (acute paranoid schizophrenia) deteriorated shortly after discharge from the impatient service (approximately 2 months). Both were then treated with neuroleptic medication.

TABLE 1
Mean Oral Frequency Counts

Patient	Before ECT	During ECT	After ECT
1	60.7	52.8	47.7
2	140.1	125.1	114.1
3	81.9	101.6	103.2
4	20.1	14.8	31.7
Mean	75.7	73.6	74.2
Mean excluding case 4	94.2	93.2	88.4

Discussion

The findings reported in this study suggest that ECT had a negligible effect on the dyskinetic process. In one individual patient the dyskinesia significantly worsened during the post-ECT period. This particular patient had as high as a threefold difference in dyskinesia ratings during the baseline period, whereas the other three patients' baseline ratings varied less than 20%. Gardos and Cole (2) recently reported on patients whose dyskinesia fluctuated markedly in a short period of time even when their dosage of medication was unchanged. The authors thought this might cause false positive or false negative results and suggested eliminating such patients from studies on dyskinesia (2). When patient 4 is removed from consideration, the finding that ECT has a negligible effect on dyskinesia appears stronger (table 1). This stands in contrast to recent work demonstrating that ECT has a beneficial effect in Parkinson's disease (7, 8).

A real dilemma exists on how to treat the psychotic patient with tardive dyskinesia. Although tardive dyskinesia is frequently irreversible, recent reports have suggested that stopping the neuroleptic medication in patients whose tardive dyskinesia is in the early stages can reverse the symptoms (7). The importance of making every attempt to reverse tardive dyskinesia is highlighted by a recent report suggesting an increased mortality in tardive dyskinesia patients (10). It is our hope that an alternative antipsychotic therapy can be used in psychotic patients with tardive dyskinesia which would not negatively influence their iatrogenic disease. This report suggests that ECT might be such a treatment for some patients.

Post-ECT Asterixis Associated with Primary Hyperparathyroidism

BY MAURICE W. DYSKEN, M.D., AND ANGELOS E. HALARIS, M.D., PH.D.

Asterixis is a neurological sign commonly associated with hepatic encephalopathy. First described in 1949 by Adams and Foley (1), asterixis consists of quick, asynchronous, flexion-extension movements of the hands from an initial position of hyperextension at the wrists. These involuntary movements represent momentary lapses in the patient's ability to sustain a fixed posture and are associated with electromyographic evidence of periodic electrical inactivity. Asterixis may also appear in a variety of nonhepatic, metabolic encephalopathies and has been reported in patients with chronic pulmonary insufficiency, uremia, malabsorption syndromes, bromism, and magnesium deficiency (2). In this paper we will report on a patient who developed post-ECT asterixis, a complication that led to the detection of primary hyperparathyroidism.

Case Report

A 48-year-old woman with no previous psychiatric complaints entered the hospital with a 10-day history of manic behavior characterized by pressured speech, flight of ideas, hyperactivity, and preoccupation with religious concerns. She gave a positive family history for affective illness: both her father and brother had committed suicide during depressive episodes. Physical examination including neck palpation was entirely normal. Serum calcium was 10.8 mg/dl, which is at the upper limit of normal (8.8–11.0 mg/dl). Protein electrophoresis was entirely normal. She was diagnosed as manic-depressive, manic type, and started on 300 mg of lithium carbonate t.i.d. Because of persistent nausea and vomiting, lithium carbonate was discontinued at the end of 10 days and the patient was treated with 20 mg of trifluoperazine daily. Her elevated mood returned to normal over the next 3 weeks and she was discharged on 50 mg of fluphenazine decanoate every 2 weeks.

Dr. Dysken is Research Associate (Assistant Professor of Psychiatry) and Dr. Halaris is Assistant Professor of Psychiatry, University of Chicago. Address reprint requests to Dr. Dysken at the Illinois State Psychiatric Institute, 1601 West Taylor St., Chicago, Ill. 60612.

The patient functioned well at home for approximately 10 days and then began to experience depression associated with anorexia, insomnia, fatigue, and suicidal thoughts. She was rehospitalized 2 weeks after discharge with a diagnosis of manic-depressive illness, circular type, and was given lithium carbonate, 300 mg t.i.d. She tolerated the drug this time because 250 mg of trimethobenzamide (Tigan) was given 30 minutes before lithium was administered. A steady-state plasma level of 1.04 mEq/liter was obtained on 1,200 mg/day of lithium carbonate. The trimethobenzamide was discontinued after 1 week without recurrence of nausea or vomiting. Because the patient's depression was quite severe and was characterized by marked weight loss and psychomotor retardation, ECT was started on the 10th day of lithium carbonate treatment. ECT was administered three times a week (Monday, Wednesday, and Friday) while she was maintained on lithium carbonate. A total of 10 ECTs was given: the first was bilateral and the subsequent ones were all unilateral over the nondominant hemisphere. Pretreatment medications included intravenous atropine, 0.4 mg; thiopental, 75 mg; and succinylcholine, 40 mg; as well as nasal oxygen. After the third ECT the patient showed increased interest in her appearance and in ward activities. Because of increasing agitation she was started on thioridazine, 10 mg t.i.d. three times a day and 50 mg at bedtime, and experienced relief of tension and less frequent periods of wakefulness during the night. Her depression continued to improve with each ECT. Immediately upon regaining consciousness after the 9th and 10th ECTs, she developed bilateral upper limb asterixis that lasted for approximately 2 hours.

Since the development of asterixis suggested a metabolic encephalopathy, a search for the underlying cause was initiated during the period of asterixis after the 10th ECT. Arterial blood gases and pH were normal. Assisted ventilation during the 10th ECT had appeared adequate. The patient had no history of liver disease, and liver enzymes and blood ammonia level were normal. Serum glucose, BUN, and magnesium were all within normal limits. The EEG showed generalized slowing, a pattern consistent with the presence of a metabolic encephalopathy. Skull films and a brain scan were normal. The plasma calcium, however, was above normal at 12.0 mg/dl with normal albumin, phosphorus, and alkaline phosphatase levels. Parathyroid hormone (PTH) level, determined from a sample of blood drawn 2 weeks after the

0002-953X/78/0010-1237$0.35 © American Psychiatric Association

10th ECT, was elevated at 44 μEq/ml and was associated with elevated calcium level of 11.5 mg/dl. A presumptive diagnosis of primary hyperparathyroidism was made. When we examined her chart for past calcium and phosphorus determinations, we discovered that 3 years before admission she had had a calcium level of 9.7 mg/dl and a low phosphorus level (2.4 mg/dl). Two years before admission her calcium level was 10.6 mg/dl and phosphorus was 2.6 mg/dl, and 1 year before admission the calcium was 11.3 mg/dl and phosphorus was 3.1 mg/dl. Because the patient had been medically asymptomatic, neck exploration for a parathyroid adenoma did not seem warranted at this time, and arrangements were made for the patient to be followed in the endocrine clinic after her discharge from the hospital.

Upon completion of ECT, the patient was started on desipramine, which was increased to 150 mg/day. She was discharged much improved on desipramine, thioridazine, and lithium carbonate. Thioridazine was discontinued 1 month later and desipramine was stopped 5 months later. The patient has continued on lithium carbonate for the past 18 months and has not experienced depressive or manic episodes. A repeat PTH level 1 month after discharge was 35 μEq/ml, with a calcium level of 10.5 mg/dl. These values remain compatible with a diagnosis of primary hyperparathyroidism (3).

Discussion

Since asterixis began immediately after the 7th and 10th ECTs, we conclude that ECT was necessary for the development of asterixis, but we doubt that ECT alone was sufficient to produce it. Other variables that may have interacted to produce the asterixis include the hyperparathyroidism and associated elevation in calcium, psychotropic medications, pre-ECT drugs, properties of the ECT stimulus, and post-ECT ventilatory assistance. However, the absence of any report in the literature describing post-ECT asterixis suggests that the hyperparathyroidism may have been the significant factor in the development of the asterixis.

Administration of lithium carbonate to animals and humans has been associated in some studies with no change in serum calcium (4, 5) and in others with an increase in serum calcium (6, 7). Mellerup and associates (6) examined lithium effects in thyroparathyroidectomized rats and concluded that the calcium elevation was independent of PTH secretion. It appears unlikely that lithium produced our patient's hyperparathyroidism. Calcium and phosphorus levels before lithium treatment suggest that hyperparathyroidism developed over the 3 years preceding hospitalization.

Recent studies have demonstrated a fall in urinary and serum calcium after ECT (8, 9). Carmen and associates (9) described decreases in both CSF and serum calcium after 3–5 treatments. They reported a single case in which the serum calcium decreased at 5 and 20 minutes post-ECT but returned to the pre-ECT level by 90 minutes. In another patient a modest increase in plasma PTH was measured 5 minutes after ECT, but the increased value was still within the normal range. The authors suggest that the increase in PTH is a secondary effect that results from the decrease in serum calcium. We wish to point out that in our patient both PTH and serum calcium were abnormally high, which suggests that the PTH increase was a primary rather than a secondary change. Follow-up calcium level determinations over the past 18 months have remained above normal, and phosphorus levels have continued to be below normal. These persistently abnormal laboratory values support a diagnosis of primary hyperparathyroidism.

The development of post-ECT asterixis focused attention on the possibility that an underlying metabolic disorder was present. To our knowledge, this is the first report not only of asterixis following ECT but also of an association between primary hyperparathyroidism and post-ECT asterixis.

Pyroluria: A Poor Marker in Chronic Schizophrenia

BY RICHARD CRUZ AND WOLFGANG H. VOGEL, PH.D.

Carl Pfeiffer and associates (1) claim that 30% of schizophrenics have elevated urinary pyrrole excretion indicative of higher pyrrole levels in the body. This endogenous pyrrole can combine with the aldehyde group of pyridoxal phosphate to form a Schiff's base, which complexes with zinc. The result of these reactions is a syndrome of B_6 and zinc deficiency (1). B_6 is a cofactor in the synthesis of various neurotransmitters such as serotonin, norepinephrine, dopamine, and GABA, and deficiencies in these neurotransmitters could contribute to psychoses and neurologic problems. We have tested morning urine samples from nine chronic schizophrenic patients for urinary pyrroles (the "mauve spot") by thin layer chromatography (TLC) and have evaluated these patients for the clinical picture described by Pfeiffer and associates as characteristic of pyridoxine and zinc deficiency.

Method

The urinary pyrrole analysis used was Irvine's procedure as modified by Sohler and associates (2–4) to eliminate false positives due to the presence of phenothiazine metabolites.

Internal and external standards and blanks ensured accuracy in the determination of pyrrole. TLC spots were judged positive or negative by visual comparison with internal standards. The urinary pyrrole determinations were carried out on 10 healthy controls and on a group of 9 chronic schizophrenic inpatients at Jefferson Hospital. The controls (9 men and 1 woman) had an age range of 20–47 years, with a mean of 27. The schizophrenic patients (7 men and 2 women) ranged in age from 23 to 57, with a mean of 31. All patients were taking either phenothiazines or haloperidol. The diagnosis of schizophrenia was based on a history of a first psychotic break before age 35 and at least two hospitalizations in two different years, plus at least two of the following symptoms: auditory hallucinations, delusions, flat or inappropriate affect, and looseness of associations. We looked for the following symptoms and signs, described in detail by Pfeiffer and associates (1) as characteristic of B_6 and zinc deficiency: schizo-affective type schizophrenia, history of major stress preceding the psychotic break, inability to remember dreams, sallow complexion, photosensitivity, dermatitis, cutaneous stretch marks, unexplained fever and chills, morning nausea, chronic constipation, upper left quadrant pain, barbiturate intolerance, amenorrhea, impotence, paresthesias, tremor, shaking, muscle spasms, convulsions, malformation of the knee, white spots on nails, hypoglycemia and B_6-responsive anemia.

Mr. Cruz is a third year medical student, Jefferson Medical College, Thomas Jefferson University, Philadelphia, Pa. 19107, where Dr. Vogel is Professor of Pharmacology and of Psychiatry and Human Behavior. Address reprint requests to Dr. Vogel.

The authors would like to thank Alan Sohler, Ph.D., Roy Clouse, M.D., and Robert Stolberg-Acosta, M.D., for their assistance.

Results

Table 1 shows a comparison of pyrrole test results and the Pfeiffer and associates clinical criteria for zinc and B_6 deficiency. Only 2 of the patients had positive tests for urinary pyrrole excretion. One patient could not remember dreams and the other patient had a history of constipation and amnesia. However 5 of 7 patients with negative urine tests had 3 or more of Pfeiffer's symptoms of B_6 and zinc deficiency. One female patient with a negative urine test had many of the symptoms described by Pfeiffer: her psychotic break was preceded by the stress of her father's death, she is schizo-affective and says her knees became "disjointed" during childhood, and she has sallow complexion, dermatitis, amenorrhea, and peripheral neuropathy. The patient's blood level of B_6 was normal (67 ng/ml).

Only 2 of the 10 controls were positive for pyrroles when tested again, they were found to be negative.

Discussion

It is our feeling that pyroluria is a poor marker in chronic schizophrenia for Pfeiffer's symptoms of B_6 and zinc deficiency. The comparable prevalence of pyroluria in our patient and control groups suggests that pyroluria is unrelated to chronic schizophrenia. Furthermore, the finding of both positive and negative test results in the same individual (2 control subjects) might suggest a dietary origin for pyroluria.

It is possible that Pfeiffer's observations were made on patients who had acute schizophrenic symptoms but whose overall syndrome is a disease of heme biosynthesis similar to porphyria. Pfeiffer and associates have found that patients with "pyroluric schizophrenia" have increased urinary coproporphyrin excretion (1) as do patients with porphyria (5). Patients with acute intermittent porphyria and patients with porphyria variegata may have psychotic symptoms, abdominal colic, and neurologic symptoms (5). Patients with porphyria variegata may also have symptoms of photosensitive dermatitis and barbiturate intolerance (5). Hamefelt and Wetterberg (6) found decreased blood concentrations of pyridoxal phosphate in patients with acute intermittent porphyria (AIP). No clinical improvement was found when two of these B_6-deficient patients with AIP were treated with low doses (100 mg/day) of pyridoxine. Pfeiffer and associates prescribe

"Experimental" Self-Mutilation

BY STEVEN L. DUBOVSKY, M.D.

Patients who habitually injure themselves without suicidal intent are often encountered on medical and psychiatric services. Wrist cutting is the most frequent type of self-mutilation (1, 2), but abrasion, burning, head banging, ingestion of medications and various objects, jumping from heights, hair pulling, insertion of foreign bodies into the urethra, self-enucleation, self-castration, and removal of the tongue have been reported occasionally (1, 3–5). The following case report represents a type of self-mutilation that as far as I

Dr. Dubovsky is Director of Undergraduate Education in Psychiatry and Assistant Professor of Psychiatry, University of Colorado Medical Center, 4200 East Ninth Ave., Denver, Colo. 80262.

 0002-953X/78/0010-1240$0.35 © American Psychiatric Association

know has not been reported previously and that provides some additional insights into this disturbing symptom.

Case Report

The patient was a 22-year-old man with congenital sensory neuropathy and an inability to appreciate pain, temperature, proprioceptive stimuli, and other surface sensations because he lacked peripheral sensory nerves (6). He did not know when he had hurt himself, so his injuries often went untreated, and he developed numerous chronic infections of his extremities that could be controlled only by amputation. The patient's care was further complicated because he ignored wounds or interfered with their healing by picking at them or refusing to change dressings. Angry confrontations by the surgical staff resulted in a worsening of this behavior. He eventually explained to the psychiatric consultant that if he tried to heal his wounds and failed, he would experience overwhelming disappointment and anger. He had therefore decided to make his wounds worse so that the outcome would at least be predictable.

By the time the patient was 21, three fingers on his left hand, two fingers on his right hand, and his right leg had been amputated, and he had developed chronic osteomyelitis in his left leg, which he knew would eventually require amputation. At this point, he began to cut his wrists and forearms systematically, always in different locations. He initially said that he had been depressed about the possibility of losing his remaining leg and thought that life would not be worth living without it. On closer questioning, however, he described an entirely different motive. He said that he had noticed that healing of his extremities was worse distally, and he wondered whether he would experience difficulty healing in his thighs after his left leg was amputated too, and in his arms after he lost his hands. He had decided to experiment on his arms in order to examine this question systematically. Because he thought that this would sound like a "crazy" reason to cut himself, he had decided to give a more understandable explanation, i.e., that he was suicidal. After he had satisfied himself that his wrist wounds healed quickly, this self-mutilation ceased.

A year after his left leg was amputated, the patient developed chronic osteomyelitis of his left index finger. Antibiotics did not seem to help and he asked his surgeon to amputate the finger. He was angered by the constant reminders of his body's inability to heal and felt that the finger was "only in the way." The surgeon did not feel that the patient was in a position to formulate an accurate diagnosis and treatment plan and refused to amputate. Three days later, the patient cut a hole in a shoe box and put the healthy finger inside the box. He stuck the infected finger through the hole and calmly sawed it off with a hack saw. He saved the finger in a plastic bag in the freezer for later "study."

Discussion

Unlike borderline or chronic schizophrenic patients who cut themselves to relieve feelings of depersonalization (1), lessen inner tension (7), solve genital conflicts (8), or to be reassured that they are alive by seeing or feeling their own blood, (1, 9), the patient's acts had specific "experimental" and "surgical" purposes. This unusual attitude seems to have reflected a wish to deny his inability to control his body by playing an active role in its destruction. He could then feel that he was losing body parts because it was his wish. He also acted as though only a part of himself (e.g., his finger) was incapable of healing itself and removed the helpless part by amputation.

Few psychiatrists can expect to encounter such unusual symptoms in a patient with such a severe medical disorder. However, the wish of patients who feel helpless or victimized to assert control over a part of themselves may play a role in many forms of self-mutilation.

The Catatonic Dilemma

BY IRA BRENNER, M.D., AND WILLIAM J. RHEUBAN, M.D.

High-potency neuroleptic treatment of schizophrenia can be complicated by the onset of putative extrapyramidal signs, which can be indistinguishable from catatonia (1–7). Clinicians are warned to stop medication for noncatatonic patients who become catatonic during treatment (1) because such patients are prone to serious complications, e.g., pulmonary emboli and pneumonia (7). The following case details our dilemma in treating catatonic schizophrenia and superimposed neuroleptic catatonia. To our knowledge, this combination, although it has been assumed to occur, has not been reported previously.

Case Report

A 19-year-old college student, previously in excellent health but with a family history of schizophrenia, developed increasing inability to concentrate, anxiety, anorexia, and indecisiveness several weeks before his admission. He became preoccupied with his sexual identity, and tension developed between him and his roommates regarding whether or not he should move out. He decompensated to the point that food had to be placed in front of him. He was referred to the emergency room, where he exhibited motor ambivalence, agitation, and loosened associations. He refused to be admitted and was given haloperidol, 5 mg p.o. The next day he agreed to admission; he was almost mute, with fixed staring, posturing, ideas of reference, thought rushing, and auditory hallucinations. Physical examination, CBC, SMA-12, SMA-6, EEG, CT scan, and a neurology consultation ruled out organicity. Haloperidol was increased to 30 mg/day, resulting in an acute dystonic reaction. Benztropine, 2 mg I.M., was effective in treating the reaction and 4 mg/day p.o. was added. His stupor worsened, and he demonstrated waxy flexibility, automatic obedience, rigidity, reaction at the last moment, abnormal compliance, and forced grasping. Haloperidol was increased to 80 mg/day on day 4 and amantadine, 200 mg/day, replaced benztropine. The patient became progressively more autistic and developed a "paralysis" of the left arm. He believed that moving his left side made him a woman and moving his right side made him a homosexual. Male aides made him agitated, and we wondered whether he might erupt into catatonic excitement. Amantadine was discontinued on day 7 and the patient regressed further. Urinary incontinence and food refusal coincided with family visits. The patient appeared to have difficulty with secretions and the gag reflex was decreased, although his lungs remained clear. Haloperidol was discontinued and IVs were started. By day 10, there was gradual improvement in motor activity and the patient began to eat, but his difficulty with secretions continued. His WBC increased to 16,000 and a chest X ray showed bilateral lower lobe infiltrates. Pulmonary consultants confirmed the diagnosis of aspiration pneumonia and felt that the psychiatric service had missed an underlying systemic illness that warranted further evaluation. The patient was then transferred to the medical ward for treatment.

The patient's rigidity, mutism, and posturing continued to improve gradually without medication. Penicillin, 10^7 U/day in continuous infusion, was started, and the infiltrates resolved uneventfully. He was transferred back to the psychiatric service 6 days later, at which time there was marked improvement in his rigidity and mutism. Hallucinations and thought rushing disappeared, but loosened associations, perplexity, denial of illness, and "paralysis" persisted. He also remained delusional about the consequences of moving his body. Thioridazine was instituted in a dosage of 75 mg/day, which was slowly increased to 500 mg/day over 3 weeks. At the time of discharge, his thought disturbance was improved and his motor involvement resolved, except for weakness of the left arm.

Discussion

The patient's conflict over movement demonstrated analogic action, which is seen in disorders of volition (8). Moving out of his apartment meant failure, which he equated with being a failure as a man and becoming a woman or a homosexual. He felt he would have to return home to his schizophrenic mother and brother, submitting himself to a lifetime of psychosis. Consequently, his immobility served the dual magical purposes of preventing his move and preserving his male image. The persistent weakness of his arm seemed to contain his psychosis, encapsulating his struggle over moving. Such volitional conflicts are characteristic of catatonic schizophrenia (8) and would not be seen in a pure neuroleptic-induced stupor.

As the patient's clinical course progressively deteriorated, the staff began to experience his dilemma, feeling helpless and indecisive. Distinguishing between the increasing drug side effects and the psychosis was very difficult. Did he have iatrogenic catatonia, or was his underlying schizophrenia refractory to treatment? Then, when he developed aspiration pneumonia, the staff experienced guilt followed by indignation and loss of esteem when the consultants implied we had failed and "must have missed the underlying illness." Although he improved, the patient remained psychotic and regressed when he returned to our ward. Consequently, the staff's feelings about "missing the diagnosis" were relieved, and the iatrogenic overlay became clear.

Catatonia accounts for more than 5% of first diagnoses of schizophrenia (9) and the incidence of neuroleptic-induced catatonia is estimated by some clinicians to be less than .5% (personal communication with Salman Akhtar, M.D., David Rosenman, M.D.,

Dr. Brenner is Chief Resident in Psychiatry and Dr. Rheuban is Assistant Professor of Psychiatry, University of Virginia Medical Center, P.O. Box 203, Charlottesville, Va. 22901.

The authors wish to thank Salman Akhtar, M.D., Assistant Professor of Psychiatry, University of Virginia Medical Center, for his help with the manuscript.

and William J. Rheuban, M.D.), so the probability of encountering this combination is quite small. Even though catatonic features do not appear to predispose patients to extrapyramidal effects such as akinesia and rigidity (10), high-potency drugs should be used cautiously in catatonics until methods are developed to predict those especially at risk. One possibility is assay of pretreatment urinary dopamine excretion, which is negatively correlated with the probability of developing such toxicity (10). If neuroleptic catatonia is indeed a severe extrapyramidal reaction, such measurements could identify the low dopamine excreters, who might comprise the high-risk group.

Safe Use of Haloperidol in a Patient with Cardiac Dysrhythmia

SIR: Often it is necessary to treat with antipsychotic medication patients who have cardiovascular disease. The hypotensive side effects of phenothiazines and thioxanthenes, a well-documented problem (1, 2), usually compel one to turn to another class of agents. Butyrophenones, primarily haloperidol, are often recommended because of their allegedly low rate of cardiovascular effects, both on blood pressure and the cardiac conduction system (2–4). However, evidence of haloperidol's safety is anecdotal and not well documented. It seems helpful, therefore, to report an example of the safe use of haloperidol to treat an acute psychosis in a 14-year-old boy with a severe genetic disorder of cardiac rhythm.

The patient was 13 years old at the time of his first cardiac arrest. He was admitted to the hospital 1 year later, after his third cardiac arrest, during which he had developed ventricular fibrillation, required electroconversion five times, and had also vomited and aspirated, which led to a severe pneumonia. He had had an older brother who died from a cardiac dysrhythmia and two younger brothers who were also suspected of having cardiac conduction abnormalities; there were no female siblings. He was diagnosed as having Romano-Ward syndrome (prolonged Q-T interval).

During his hospitalization he had multiple medical problems, including several episodes of cardiac dysrhythmia, sepsis, aspiration pneumonia, hypoxia, gastrointestinal bleeding, persistent hypokalemia, transient liver enzyme elevation, a positive direct Coombs' test, and agitated psychosis (presumably secondary to one or more of his other problems or medications) with apparent hallucinations. During his hospitalization he was treated at various times with cephalothin, digoxin, amikacin, chloramphenicol, intravenous lidocaine, propranolol, tocainide, cimetidine, carbenicillin, potassium supplement, amino-phylline, multi-vitamins, folic acid, antacids, and ferrous sulfate. He also received blood transfusions. His cardiac dysrhythmias included recurrent ventricular premature beats, ventricular tachycardia, supraventricular paroxysmal tachycardia, ventricular fibrillation, and multifocal bigeminy. He required a cardiac pacemaker.

During the second week of hospitalization the patient developed an agitated, delirious psychosis with apparent hallucinations. He was originally treated with a combination of a barbiturate, a narcotic, and a benzodiazepine; these provided sedation. However, when he was awake it was clear that the psychosis did not respond to this regimen. Therefore, haloperidol was administered in a previously described regimen (5), except that in this patient it was given orally through a nasogastric tube. Maintenance medication was 10 mg b.i.d. with further 5-mg doses as needed. The average daily dose was approximately 30 mg. The agitation, disorientation, and hallucinations resolved in about 3 days. Within 2 weeks haloperidol was stopped. By this time the patient's medical status had markedly improved. There was no return of psychotic or delirious symptoms throughout the remaining hospitalization or thereafter for at least 6 months (the time of last follow-up).

With the exception of a mild tremor that resolved with improvement of the medical problems, the patient had no untoward reactions to haloperidol. Specifically, there was no deterioration of his cardiac status. The successful use of haloperidol in this patient with a very severe cardiac rhythm disturbance supports previous statements that haloperidol is free of cardiovascular side effects and is the antipsychotic drug of choice in patients with cardiac rhythm disorders.

Wedded Bliss Between Professionals?

SIR: I read with dismay the article "The Successful Professional Woman: On Being Married to One" (October 1977 issue) by Theodore Nadelson, M.D., and Leon Eisenberg, M.D., in which two male psychiatrists purport to describe the joys they have found in being married to women who are also psychiatrists. They conclude, "We consider ourselves the most fortunate of men." However, the tone of the paper is so cloying and effusive that only the most naïve (or psychologically insensitive) reader would take the message at face value.

What comes across to me is a hymn of praise not to their wives and their marriages, but to themselves for being such

great guys about putting up with the inconveniences and downright foolishness inherent in their wives carrying on as though they truly are their husbands' professional peers.

The most telling vignette is the one in which L describes, with obvious delight, the way he handled himself while attending a professional meeting in the role of spouse. His idea of social grace was to upstage his wife by delivering a life-of-the-party after-dinner speech in which the big joke was the absurdity of his being cast in the role of mere faculty spouse.

My husband is a radiologist. Over the years he's been my greatest source of support. At times we've had our tensions over who's pulling, or not pulling, his/her share of the spouse, parent, and professional loads. But never have I sensed in him the kind of competitiveness that I sense in the Nadelson and Eisenberg marriages. My husband has never felt it necessary to be the star at my professional gatherings. Nor has he sought to increase his list of professional presentations or publications by writing about how capably he has dealt with me over the years.

You show-cased the article as though you saw it as a paradigm for wedded bliss between professionals. I propose you would have done better to offer it under the classic women's magazine feature: "Can These Marriages be Saved?"

JEAN L. ROBERTS, M.D.
Bedford, Tex.

Trimipramine and Relapses of Symptomatic Drinking

SIR: I have seen puzzling relapses of heavy drinking in patients given trimipramine who correspond to the diagnostic category proposed by Hagop S. Akiskal, M.D., and associates, "intermittent bipolar affective disorder" ("Cyclothymic Disorder: Validating Criteria for Inclusion in the Bipolar Affective Group," November 1977 issue).

The first, a 52-year-old man, was treated on an outpatient basis for social phobia with a variety of antidepressants, neuroleptics, and combinations of the two classes of drugs. For the past 8 years he had fared reasonably well, with only a few drinking bouts. Because of his history of chronic incapacitation and the clinical picture of agitated depression, trimipramine was started in a single oral dose of 100 mg at bedtime. He reported considerable gain in subjective well-being and demonstrated self-confidence that deteriorated into occasional paranoid vindictiveness within a few weeks. Almost simultaneously there were signs that he had resumed his secret drinking. Within about 6 weeks of the introduction of trimipramine, which was then at 150 mg/day, he was in an acute detoxification center because of legitimate fears for his own and the household's safety.

The second patient, an unemployed 35-year-old artist with a history of heavy periodic drinking, had been treated on an outpatient basis for almost 8 years with minor and major tranquilizers without too much success. Because of his underlying depression and definite periodicity, trimipramine, 75–100 mg/day, and lithium carbonate, 900 mg/day, were started. He reported a subjective increase in well-being and improved sleep within a few weeks, but within a month he slipped into an unusually heavy and prolonged episode of drinking that ended with hospitalization for a predelirious condition.

The third example was a 52-year-old laboratory technician who had been sober for almost 11 years. He had been treated for 6 years during which time he had at least two bouts of reckless spending and traveling that were controlled with phenothiazines. His presenting complaints were primarily neurotic, but he also showed a definite impulsive trait with ready vindictiveness and some paranoid attitudes. Upon recognition of the periodic pattern of the seemingly (hypo)manic episodes superimposed on chronic "anxiety-depression," trimipramine, 150 mg/day, was prescribed, and the patient reported that he felt better within a few weeks. However, he has since slipped back into fairly heavy drinking.

All of these men had a long-standing affective disturbance with discernible periodicity, compounded by dipsomania. Introduction of trimipramine to treat the anxious depression uniformly produced initial subjective improvement only to result in a return to heavy drinking within about 4 weeks.

Is this merely a series of coincidences? Do the bouts of drinking represent (atypical) manic episodes that could be triggered by any tricyclic antidepressant? Could we suspect a similar idiosyncratic reaction to trimipramine in all recidivist alcoholics? Or is it that the combination of intermittent bipolar disorder with a history of alcohol abuse provides an unfortunate metabolic background for the specific dibenzazepine drug?

ANDRZEJ KUBACKI, M.D.
Bathurst, N.B., Canada

Dr. Akiskal Replies

SIR: Dr. Kubacki's clinical vignettes are not presented with sufficient detail to enable one to decide whether they exemplify what my associates and I describe as "cyclothymic disorder." Dipsomania is a known clinical indication of bipolar disorder, occurring more commonly during the hypomanic or manic phase. Nevertheless, it is difficult to determine whether these relapses of drinking behavior represent a hypomanic "equivalent" in the absence of other clinical features suggestive of a bipolar disorder. From the available information, it would be more parsimonious to suggest that the patients reported were simply experiencing a return of pretreatment behavior.

Pharmacologically induced hypomania has been reported with the tricyclic drugs, monoamine oxidase inhibitors, L-dopa, sympathomimetic drugs, ECT, and sleep deprivation (1–3). The available evidence suggests that it is generally limited to bipolar depressives. The occurrence of this phenomenon with drugs or procedures that suppress REM sleep or mobilize limbic system catecholamines suggests that REM suppression or neurotransmitters involved in this process are integral to the switch process from depression to mania. However, drugs with relatively selective action on the serotonergic system (e.g., 5-hydroxytryptophan plus peripheral decarboxylase inhibitor or tryptophan plus an MAO inhibitor) have also been reported to induce hypomanic behavior (4). I am not aware of reports of trimipramine-related hypomania. However, since it suppresses REM sleep, like other tricyclic antidepressants, it would be logical to expect a pharmacologically induced shift from depression to hypomania upon trimipramine administration.

Speech Blockage: Therapeutic Side Effect?

SIR: In their article "Speech Blockage: A Tricyclic Side Effect" (May 1978 issue) Alan Schatzberg, M.D., and associates stated that "to our knowledge this tricyclic side effect has not been described in the literature." This effect was described in my paper titled "Anxiety Revisited" (*American Journal of Psychoanalysis*, volume 37, pp. 299–308). On page 306 of the article I stated, "Some of my patients taking antidepressive drugs (tricyclics) have described forgetfulness and difficulty in word or idea finding; this may help break the circular associative circuit both in obsessive-compulsive symptoms and in depressions."

I did not emphasize this as a side effect but more as a therapeutic effect. I would assume that a therapeutic effect can blend into a side effect depending on the sensitivity of the particular patient to the effect, the quantity of tricyclic, the specific tricyclic (in any patient the response and side effects differ with different tricyclics), and other drugs taken simultaneously. Other variables that can cause episodes of time-related blocking are whether the tricyclic is taken on an empty stomach or as a single bolus. I have always been fascinated by so-called side effects that in a different context are called therapeutic effects (for a discussion, see reference 1).

JACK SCHNEE, M.D.
Briarwood, N.Y.

Dr. Schatzberg Replies

SIR: We read Dr. Schnee's letter with great interest. It has been our feeling that tricyclic antidepressants may have significant effects on various cognitive functions including learning and memory (1). The symptoms described by Dr. Schnee appear similar to those described in our communication. We must point out, however, that many of these patients experienced the effect as a hesitance in speaking rather than an inability to think of a particular word. This phenomenon may be different from certain forms of anomia or aphasia, but it is conceivable that the various effects noted are all related under one umbrella. An important difference between our report and Dr. Schnee's is that our patients who experienced speech blockage or some memory disturbance were uncomfortable and complained that the symptoms interfered with their functioning.

It is difficult to cull from the literature all reports of drug side effects. However, to our knowledge Dr. Schnee's paper appeared while ours was in press. We also received an interesting letter from Dr. Francis Kane, who apparently described this phenomenon some 14 years ago (2), certainly before our paper was in press! Dr. Kane's report raises another dimension to this phenomenon. Cited are references to a syndrome of stammering, jerky speech, and involuntary jerks of the head and extremities (3, 4). These have occurred with imipramine-phenothiazine combination and with imipramine overdose. This phenomenon is similar to the myoclonic seizures on high-dose chlorpromazine-imipramine combination, described by Kramer and associates in 1962 (5). This phenomenon may be quite different from our patients', who did not show such myoclonus. Again, however, an argument could be made that the two phenomena are related in some way. At any rate, it is important for clinicians to be aware of less frequent untoward reactions to the tricyclics, and we were pleased to read the letters.

An Educational Approach to Short-Term Hospitalization

SIR: In "Brief Versus Standard Hospitalization: The Differential Costs" (June 1978 issue). Jean Endicott, Ph.D., and associates presented a good case for brief hospitalization. This concept has been successfully used at the Mandala Center, a private psychiatric hospital in Winston-Salem, N.C., where the average length of stay is 18 days. The focus on short-term treatment uses a novel approach to mental illness.

The patients attend mandatory classes six times a week for 1 hour. Classes, which are both didactic and experiential, cover the following topics: "Thinking Yourself Out of Depression Using the ABCs of Rational Emotive Therapy" (RET), "Assertive Training" (AT), "Transactional Analysis" (TA), "Coping with Stress," and "Relaxation Training."

These five areas are taught each week, so therapists and patients talk the same language. The hospital bookstore sells self-help books dealing with each of these topics, and patients are encouraged to read them as part of their daily homework assignments. Families are encouraged to read the same books. Therapy sessions focus on the patients' problems along with the self-help techniques that they have learned. Because the average length of stay is only 18 days, the treatment is intense, with a focus on increased self-help skills to use outside the hospital setting. An example of this treatment approach follows.

A 37-year-old woman came to the hospital with extreme depression resulting from a poor marital relationship and boredom with her life. In addition to antidepressants, the treatment program called for daily education classes, activi-

ty therapy, individual sessions with the therapist, and group sessions with her psychiatrist. During individual and group sessions, the focus of therapy was on her negative cognitions leading to depression (RET) and her helpless "child" ego state (TA). Once a degree of insight was obtained, the action stage of therapy involved assertive techniques (AT) and relaxation exercises to help her cope with her anxiety. Her base of knowledge was the education classes, which the therapist and psychiatrist channeled to her personal situation. The patient was not only treated by mental health professionals but was also able to talk with some of the other patients about her problems because they all spoke the same "language."

The use of education groups can be a valuable adjunct to therapy; patients can learn basic coping strategies that are then made specific to their own personal problems. Follow-up with patients supports the assumption that this is one of the most helpful aspects of the brief hospitalization treatment program.

Winston-Salem, N.C.

CHAMPUS Payment Limitations

SIR: I would like to respond to the Letter to the Editor on "CHAMPUS Coverage" (April 1978 issue) by Jonathan G. Solomon, M.D. Dr. Solomon objects to CHAMPUS limitations of payment for five visits per week. It is hard to believe that this is not more than adequate reimbursement.

Analyzing the letter briefly, Dr. Solomon's emotionalism is evident in such words as "arbitrary," "unwarranted," "galling," and "intrusion." He states that his hospital (Bayberry Psychiatric Hospital) typically has provided 7–11 hours of therapy per week; undoubtedly the hospital has been reimbursed for this. It is hard to see justification for that kind of treatment and one wonders if anyone can afford to be ill. The only way one could pay for such therapy is through third-party payments, i.e., CHAMPUS, which Dr. Solomon is so vehemently berating.

It would seem he wants it both ways, and has been used to getting it so in the past. I can think of better places for my tax dollar than the situation Dr. Solomon describes at Bayberry Hospital.

E. WILLIAM HAUSER, M.D.
Newport Beach, Calif.

Dr. Solomon Replies

SIR: I plead guilty to the charge of emotionalism on the important issue of the intrusion of third-party carriers into the doctor–patient relationship. The thrust of my previous letter was to protest the arbitrary curtailment of insurance coverage by CHAMPUS for psychiatric patients. I strongly feel that psychiatric patients are entitled to medical care on the same basis as other medical patients and should not be discriminated against. Further, depriving psychiatric patients of mental health care is an unproductive attempt to effect cost-curtailment because they then overutilize medical facilities (1–2).

It is unclear what Dr. Hauser means by "that kind of treatment" but he seems to object to spending 7–11 hours a week with patients and feels that 5 visits a week should suffice in treating hospitalized patients. It seems peculiar to restrict the therapy portion of a 168-hour week to an arbitrary maximum of 5 hours. There is always the chance that CHAMPUS will discover that it is cheaper to establish a minimum of 4 hours weekly, and then perhaps none at all. The determination of the number of reimbursable therapy hours per week seems an unwarranted intrusion by third-party carriers who are not licensed to practice medicine. Their business is insurance; their primary interest to curtail costs. The clinician's primary goal is to provide quality health care. A conflict of interest may ensue.

There are safeguards in existence to prevent abuse of services. For example, at Bayberry Psychiatric Hospital there are overviews by an active utilization review committee, the Colonial Virginia Foundation for Medical Care, audits by the Joint Commission on Accreditation of Hospitals, Medicare and others, and chart reviews by insurance companies who can and do request photocopies of entire charts. Thus, only those patients who require intensive treatment are hospitalized.

In a previous communication (3) I expressed the view that a wide variety of community-based alternatives to hospitalization should be available. Unfortunately, CHAMPUS recently curtailed the benefits of partial hospitalization from 5 days a week to 2. So much for "The Paradoxical Underutilization of Partial Hospitalization" (4), a modality of therapy that is effective and less costly than residential treatment but which is undermined by the counterproductive policy of the carrier.

I recognize the importance of third-party carriers but protest a unilateral determination of medical practice. I feel the health care providers should be consulted with rather than informed of policy directives. We are not yet salaried employees of the government and may have contributions to make in establishing policies. Accountability should be a two-way street and is best served by an ongoing dialogue between the carriers and the health care providers, whose goal is to establish policies that maximize the quality and availability of care while restraining escalating costs. The practice of medicine is sufficiently challenging and arduous without an adversary relationship between the medical profession and the insurance industry.

Persistent Lithium-induced Nephrogenic Diabetes Insipidus

SIR: Nephrogenic diabetes insipidus is an unusual but important side effect of lithium carbonate therapy. It is typically associated with nontoxic serum levels of lithium, is thought to result from an idiosyncratic effect of lithium or the biochemical mediation of the action of vasopressin in the

renal tubular cell, and is generally thought to clear within three weeks of discontinuation of lithium therapy (1–3). A case we reported in the medical literature (4) and another case report (5) indicate that nephrogenic diabetes insipidus secondary to lithium does not always clear rapidly and may, in fact, persist for up to 20 months after lithium has been discontinued.

We are drawing attention to this because, to our knowledge, persistent lithium-induced nephrogenic diabetes insipidus has not been reported in the psychiatric literature. Awareness of its existence may be of considerable clinical value in the management of lithium-associated polyuric and polydipsic states that do not clear with termination of lithium therapy, especially in view of the recognized efficacy of thiazide diuretics in such circumstances.

Tardive Dyskinesia or Not?

SIR: I consider the article "A Survey of Tardive Dyskinesia in Psychiatric Outpatients" by Gregory M. Asnis, M.D., and associates (December 1977 issue) to be sufficiently misleading as to require some discussion. The central issue is whether the condition the authors evaluated was in fact tardive dyskinesia. The bulk of the evidence indicates that it was not.

Tardive dyskinesia, although not precisely defined, is generally considered to be a dyskinesia associated with long-term use of neuroleptics. Typically, it worsens on neuroleptic withdrawal, improves on reinstitution of neuroleptics, and is often worsened by anticholinergics. It must be distinguished from a variety of other dyskinesias, some drug-related, some not.

The paper by Dr. Asnis and associates reports no association between years of neuroleptic use and the presence of dyskinesias (in fact, the dyskinetic group had nonsignificantly fewer years of use). This suggests that the dyskinesias involved were not tardive dyskinesia; if a dyskinesia results from long-term neuroleptic use, one would expect a correlation between presence of dyskinesia and years of use.

Similarly, the fact that age did not correlate with the presence of dyskinesia and the trend (not statistically significant) suggesting that the use of antiparkinsonian agents was associated with a lower incidence of dyskinesia indicate that the condition under investigation was not tardive dyskinesia.

This issue is of considerable importance. Studies of tardive dyskinesia should carefully define the condition in order to obtain homogeneous populations. Factors such as response to neuroleptic withdrawal and reinstitution and response to anticholinergics or to dopamine agonists such as amphetamines can help to identify relatively homogeneous subgroups of dyskinetic patients and perhaps to define tardive dyskinesia more precisely. The approach used by Dr. Asnis and associates lumps together patients with dyskinesias of various etiologies, which will retard any efforts to understand the pathophysiology underlying tardive dyskinesia. Moreover, calling these various dyskinesias "tardive dyskinesia" and claiming a 43% prevalence of tardive dyskinesia in psychiatric outpatients will alarm many psychiatrists unnecessarily. Certainly, psychiatrists should be aware of the possibility of tardive dyskinesia, but the dyskinesias discussed by the authors have no proven relationship to classically described tardive dyskinesia, which is often irreversible and hence of considerable concern.

Finally, mention might be made of some of the difficulties involved in the use of videotapes as described in the article. The authors report excellent reliability, but this must be distinguished from validity. Their raters clearly agreed on whatever they were measuring, but there is no evidence that what they measured was tardive dyskinesia. Moreover, the person making the videotapes apparently was not blind to whether a patient was dyskinetic or not. Naturally, when videotaping a dyskinetic subject, one would attempt to demonstrate the dyskinesia as clearly as possible and would look for moments of dyskinesia to videotape. This would not be the case with control subjects, although some dyskinetic-like symptoms would be expected occasionally in normal controls. Therefore, the apparent distinction between dyskinetics and normals might be an artifact of the selective attention of the person doing the videotaping.

JEFFREY A. MATTES, M.D.
Forest Hills, N.Y.

Dr. Asnis Replies

SIR: Dr. Mattes suggests that there are commonly accepted associated findings for tardive dyskinesia, i.e., years of neuroleptic use, age, and concurrent use of antiparkinsonian medication. Because our survey did not support these associations, Dr. Mattes suggests that we were not evaluating tardive dyskinesia. However, the literature includes conflicting evidence on the role of these factors in tardive dyskinesia (1). The explanation of these controversial findings in the literature is far from clear, although diversity of study populations may have been a factor.

In our study, we carefully reviewed recent medical history, physical examinations, laboratory assessments, and family history to rule out other causes of dyskinesia. No cases of endocrinopathy, heredodegenerative disease, or other medical illnesses could be identified that might have presented as a dyskinetic syndrome. I agree with Dr. Mattes that further studies are needed to understand the pathophysiology of tardive dyskinesia; this was not the intent of our survey. It is naïve to believe that various pharmacologic challenges will separate tardive dyskinesia from other dyskinesias. Within the syndrome of tardive dyskinesia, systematic evaluations with dopamine and acetylcholine agonists and antagonists have revealed varying responses, indicating a heterogeneous disorder (2).

In terms of the evaluation process, Dr. Mattes suggests

that the person who did the videotaping might have "tipped" the raters, since he had already decided whether the patient had dyskinesia. We doubt that this was the case. The technician who recorded the evaluation did not know which patients had dyskinesia and recorded every subject in a standardized way. Most dyskinetic patients had dyskinetic movements not only during the structured part of the exam but also during the 1- to 2-minute observation period, when only the patient was present and videotaped, and all raters concurred on dyskinesia during the latter period. The point is highlighted by the fact that one patient with tardive dyskinesia demonstrated dyskinetic symptoms only during the observation period in which all three raters independently concurred.

Finally, Dr. Mattes is concerned about psychiatrists being alarmed "unnecessarily" by our report. We found that 10% of the dyskinetic population, or 4% of the survey population, had moderately severe dyskinesia; the remaining cases of dyskinesia were of minimal or mild severity. It has been suggested that dyskinesia of minimal or mild severity and of possible recent onset may be readily reversed by discontinuing antipsychotic medication or lowering the dosage (3, 4). For this reason, careful examinations to detect early signs of dyskinesia should be a routine part of psychiatric evaluations of patients treated with neuroleptics. Until the clinician has more guidelines as to which patients are most vulnerable, every patient taking neuroleptic medication must be viewed as susceptible to tardive dyskinesia. Part of good patient care should be an "overconcern" for the development of this syndrome.

Positive Side Effects of Lithium?

SIR: The article by Sahayl J. Nasr, M.D., and Robert W. Atkins, M.D., on "Coincidental Improvement in Asthma During Lithium Treatment" (September 1977 issue) in association with the observations of Peter L. Putnam, M.D. (Letter to the Editor, March 1978 issue) concerning remission of dermatologic symptoms in two patients with eczematoid dermatitis treated with lithium prompted us to report another possible "positive" side effect of lithium observed in two patients with seborrheic dermatitis.

The dermatologic symptoms of a 63-year old manic-depressive man cleared completely 1 month after initiation of prophylactic lithium treatment and have not reappeared during a 5-year follow-up. A similar effect was observed in a 32-year-old schizophrenic woman with severe seborrheic dermatitis who was treated successfully with low doses of lithium for her premenstrual tension syndrome. It is worth noting that remission of both premenstrual and dermatologic symptoms was achieved with a lithium dose of only 300 mg/day, for one week before expected day of menstruation.

We are currently pursuing the issue further by conducting a double-blind investigation on the effect of low doses of lithium carbonate on nonpsychotic patients with seborrheic dermatitis.

Mental Health Services in HMOs

SIR: In "The External Provision of Health Maintenance Organization Mental Health Services" (June 1978 issue) David J. Muller, M.D., offers unsubstantiated opinions about HMOs. My experience as a director of integrated mental health services at the Harvard Community Health Plan (HCHP) since 1969 leads me to believe that the comparison of alternative models must be addressed objectively.

How are "quality," "flexibility," and "personal care" superior in Dr. Muller's clinic? He does not cite norms of staff training or experience, individual or group performance standards, supervisory practices, evaluation of treatment outcome, quality control mechanisms, or organized consumer input—features of many HMOs. Contractual negotiations seem an insufficient substitute.

Although I find many statements in the article objectionable, two oversimplifications require response. The first relates to cost: If "cost to the HMO" is less (no numbers are given), what about cost to the member?

In stating, "When the benefits are used up, there may be insufficient motivation to pay out of pocket and continue therapy," and "The initial sessions may therefore have been wasted," Dr. Muller ignores the vast literature demonstrating effectiveness of brief treatment. With staff motivation, treatment can be planned so that most patients can be treated within insurable limits. At HCHP, where extended psychotherapy is available, less than 1% of patients seen require treatment beyond the benefit limit of 20 sessions a year. A system using prepaid benefits to introduce patients to fee-for-service treatment will be inexpensive to the HMO and profitable to the clinic but expensive for the member.

Capitation payments go farther if fewer "heads" show up. Current estimates suggest that 10%–15% of the population may require psychiatric services (1). A cost/benefit assessment should include numbers referred and seen, cancellations, and no-show rates. At HCHP, 12% of members who use health services in a year come to the mental health service. Combined cancellation and no-show rates are less than 10%, and over 82% of patients referred show up. Other external services report similar experience (2). Comparison figures from Dr. Muller would be of interest.

The second area I would like to address is liaison. A number of authors have urged shared responsibility for mental health care (1). In a medical setting, where doctors and nurses see many psychological problems, this must include willingness to diagnose and treat common disturbances as well as readiness to refer when necessary. The notion that "at least monthly conferences" with HMO physicians will adequately support such efforts is naïve. At HCHP, approximately 30% of medical patients receive a diagnosis of emo-

tional disturbance during a year; half are treated by the medical provider, half are referred. Mental health staff support this function by spending 10%–20% of their time in liaison activities and joint programs. Physical contiguity facilitates this.

Dr. Muller's arguments for an autonomous, cohesive mental health group, with control over staff appointments and training, programmatic decision making, and a portion of the budget, are compelling. These factors characterize our system and are essential. I agree with his concern about softening the medical model. Insofar as mental health professionals can make such a contribution, this calls for a greater presence, visibility, and influence in the medical setting, not for leaving it.

In summary, I believe that generic conclusions about HMOs should be withheld pending data that permit meaningful comparisons.

MICHAEL J. BENNETT, M.D.
Boston, Mass.

Dr. Muller Replies

SIR: I would like to reemphasize a major point of my paper. Any feature that the HMO wants in its mental health services can either be incorporated into its own internal department or specified in the contract with an external group. This could include many of the considerations Dr. Bennett emphasizes in his letter, such as staff training and experience, supervisory practices, evaluation and outcome studies, quality control, organized consumer input, extensive liaison services, and as much presence, visibility, and influence as desired. With these and other features equalized, I feel the autonomy and incentive of the external group give it a real advantage. Having been on both sides of the fence, I can state this definitely. Cost to the member is the same with an internal or an external group. When the HMO coverage is exhausted, the member must pay out of pocket regardless. I thank Dr. Bennett for his comments.

DAVID J. MULLER, M.D.
Denver, Colo.

Using Phylogenetic Mechanisms in Classification

SIR: We would like to comment on "A New Method of Classification for Psychophysiologic Disorders" by John G. Looney, M.D., and associates (March 1978 issue). The dilemma of classifying psychophysiologic disorders has been one of choosing between a characterologic determinant responding to an environmental situation and the resulting dysfunction of a target organ.

We propose an alternative solution. In our attempts to establish the biological underpinnings of psychophysiologic disorders, we have been concerned with the phylogenetic mechanisms that underlie their emergence. We see these as innate responses that are now inappropriate but were once adaptive.

For example, an irritable bowel syndrome becomes flight reaction, abortive and partial, manifested by increased evacuation of large bowel and bladder; spasms of the neck muscles become dominance/submission conflict, manifested by spasms of the muscles that raise and lower the head; angina pectoris becomes mock death reflex, abortive and partial, manifested by spasms of coronary arteries; and chronic indigestion becomes flight reaction, inhibited, resulting in chronic anxiety and manifested by impaired secretions of the upper alimentary tract.

We even have a place for the hypochondriac within this schema: impaired filtering of vegetative sensory stimulation (target organs are skin, heart, abdomen, etc.), cognitively elaborated as "cancer," "tuberculosis," or unspecified illness.

This is but a sampling. We are aware that this novel approach could be considered too controversial to use as a classificatory scheme; nonetheless it permits the use of ethologically verifiable instinctual response systems, placing the symptoms into a biological context, alludes to an open-ended stressor that sets the mechanism into action, and allows the avoidance or inclusion of metapsychological concepts depending on whether the emphasis is on a medical or psychological model.

Correction

In the August 1978 issue there was an error in "The Prevalence of Schizophrenia: A Reassessment Using Modern Diagnostic Criteria" by Michael Alan Taylor, M.D., and Richard Abrams, M.D. The reference to the study by Weissman and associates (cited as reference 14) in the last sentence of the first paragraph of the Inpatient and Outpatient Studies section (p. 946) should appear in the Population Studies section. The last sentence of Inpatient and Outpatient Studies should therefore refer to 8 different admission prevalence figures (range of 0.6%–6.7% is unchanged).

The staff regrets this error.

Am J Psychiatry 135:10, October 1978

BOOK REVIEWS

The Treatment Techniques of Harry Stack Sullivan, *by A.H. Chapman, M.D. New York, N.Y., Brunner/Mazel, 1978, 229 pp., $13.50.*

Some of Sullivan's followers will not like it, but Sullivan is revealed in Chapman's new book as a closet Adlerian. Perhaps neo-Adlerian would be a more acceptable term for Sullivan, who all too often is given the ill-fitting label of neo-Freudian. Sullivan was neo-Adlerian to a degree—not entirely. He reflected the contributions made by the behavioral sciences of his era: the social behaviorism of George Herbert Mead and the American pragmatic philosophers; the study of face-to-face relationships done by Charles Horton Cooley, Robert E. Park, and the rest of the Chicago school of sociologists; the linguistic and cultural relativism of Edward Sapir and other anthropologists; and the rejection of libido theory and other metapsychological efflorescences in Freudian orthodoxy by "cultural" psychoanalysts such as Karen Horney and Clara Thompson. Unlike Adler, Sullivan steered clear of Marx and socialism and stayed close to the liberal capitalist ethos. Like Adler (and Adolf Meyer, for that matter), Sullivan preferred the least ornate explanation that could be given of what goes on between therapist and patient.

Sullivan and Adler both put a premium on the recent past rather than the remote past. Sullivan was not afraid to deal with thinking as well as feeling because human beings do have heads. Like Adler, Sullivan saw the importance of self-esteem and fear and the compulsive tendency that patients have to write scripts of jargon and obfuscating self-glorification when they are upset. However, Sullivan tried to bring peace instead of the more Adlerian sword of confrontation when he dealt with shy, overly intellectualized, fearful human beings who were patients. He strove to have the patient more comfortable by the end of each session. Sullivan acknowledged, as did Adler and Freud, the importance of formations of self-esteem during infancy and childhood and how these early attitudes of self regard or patterns of interpersonal coping could recur in bad times during later life to intrude and distort contemporary relations of individuals. If calling these "parataxic distortions" seemed cumbersome at the time of Sullivan's promulgating the term, today it seems fully salutary and reasonable to have the idea if not the term. Again, like Adler, Sullivan originated ideas that have permeated psychiatric thought, Sullivanian or otherwise. One trusts that the benefits derived by patients outweigh the neglect so many show in paying tribute to Sullivan, who did the initial working through of many important views about the means and techniques of therapy.

Never wholly consistent about it, Sullivan pontificated that intrapsychic identity is fictive, that only interpersonal relations are real, and that a person is defined by his other security operations plus his or her dynamisms. He played down the individual side of humanism but played up sociability and relatedness. Thus Sullivan is a prominent figure in social psychiatry and relationship therapy.

Chapman's codified presentation of the essence of Harry Stack Sullivan's treatment techniques has great virtue merely because it simplifies the murky prolixity of the original. It is a condensation and refinement that will be very useful for all nondoctrinaire psychotherapists willing to think above all of the mentally ill patient's rights to love, care and improved social functioning. The patient is put ahead of all theoretical expectations in the Sullivanian approach. The patient is treated gently. The patient needs competent professional help but is unfailingly respected as a person. The therapist also has "needs" or values that cannot be overlooked, however much the therapist's yearnings have to be curbed in a professional career as a psychotherapist, Sullivan said. Chapman conveys Sullivan's tenet that simple humanness furnishes the underpinnings of a professional, technical, expert, almost acrobatic interaction between a therapist and patient—so that the therapy enterprise is both interactive and real while it is professional, delimited, and artificial.

A clear writer who gets right to the point, Chapman has us by page 2 into the ways Sullivan taught to induct a patient into the collaborative role required in psychotherapy. From there (until the flagging chapter 10) the pace is brisk, the tone bright, and the message elucidating. The present tense use of "Sullivan says" gives one pause occasionally but only momentarily because the reader recalls that Sullivan has a vital influence that endures. When questioned about his use of the present tense in referring to George Bernard Shaw, as if Shaw had not died in 1950, Archibald Henderson (the mathematics professor named by Shaw to be his official biographer) answered, "Shaw never dies." So it seems also to be in Chapman's attitude about Sullivan.

Sullivan's therapy-related views are succinctly delivered—views about the psychiatrist as a participant observer, his stress on the interpersonal or on self-esteem, his concepts of dynamisms and security operations, his admonitions that therapists be thrifty about time, his setting up the goal of enlarged awareness of interpersonal functioning, his insistence on details and examples and allowing very slight desensitizing anxiety (adumbrating behavior therapy operations), and his seeing "consensual validation" as a process instead of an event of accord or agreement.

Sullivan rejected some of the grosser and more implausible psychodynamic formulations based on medical mechanics as the font of metaphors. However, he kept to an airy physics vocabulary when he stated his postulates about energy transformations in human motives ("dynamisms"). Sullivan held that security operations can be healthy as well as unhealthy, but his view of man was not much less struggle-filled than that of Sigmund Freud. Sullivan also saw patients as striving, coping, defending, and fighting to ward off malignant forces that impinged on their lives. Sullivan hardly foreshadowed Maslow by dwelling on human potentialities or on the human drive to self-actualization; instead, he was clinical and problem focused. A little romantic optimism inhered, nonetheless, in his view that a person freed of distortions can unleash "a tendency toward health."

Although Chapman portrays Sullivan correctly as a therapist who knew that oppression exists, it seems to me that both Chapman and Sullivan err when they approvingly furnish examples of a therapist asking a patient about the motives or feelings of a third party (pages 9, 11, 14, 15, 29, and throughout): For example, Do you think your father found this gratifying? Was your mother fearful? Was your mother afraid of arousing irritability in other people? Did your mother think you were the only person who did poorly in school? What else was happening in your mother's life to make her so irritable? In my opinion it is a cardinal rule that a patient may feel exploited by others, but a falsifiable hypothesis for deriving consensual validation does not pull in questionable speculations about the motives and goals of people not present in the consulting room. It is always easier to talk about Fred Martin's problems than one's own (p. 43).

As a fine Sullivanian himself, Chapman adheres to common sense and brevity to create a work that is laden with literary virtues and is a practical aid to psychotherapists. Chapman is disinclined to overstate his case or to overpraise Sullivan. He does not vulgarize Sullivan either. Chapter 11 holds a refreshing synopsis of Sullivan's life and writings and a genuinely useful, not overpowering bibliography is included at the end of the book. Chapman's writing is gifted, pure and simple. The good design and typography of the book serve to give a dash of lagniappe to an extremely worthwhile primer on psychotherapy in Sullivan's mode.

Megavitamin Therapy: In Reply to the American Psychiatric Association Task Force Report on Megavitamins and Orthomolecular Psychiatry, *by A. Hoffer, Ph.D., M.D., and H. Osmond, M.B. Regina, Sask., Canada, Canadian Schizophrenia Foundation, 1976, 123 pp., $3.50 (paper).*

The history of medicine is scarred by a variety of controversies that have served more to smear reputations than to further our understanding of illness and its manifestations. The megavitamin treatment of schizophrenia is a superb example of such a controversy. The American Psychiatric Association appointed a task force that reported on the use of megavitamins for the treatment of schizophrenia. The task force concluded that there was no compelling scientific evidence that megavitamins were useful (1). This report was quite influential in diminishing the interest, let alone enthusiasm, of most American psychiatrists for the use of vitamins in high doses for the treatment of schizophrenia. Hoffer and Osmond, two of the leading proponents of this approach, have written a rebuttal of approximately 50 pages. This is supplemented by another 70 pages of appendixes that the authors feel support their position.

The tone of the volume is at best polemical and frequently deteriorates sharply to a level that has no place in scientific discourse. There is nothing to be gained by my adding more acrimony to that which has already entered the published literature. The authors argue that the task force members were biased and dishonest. They argue that the task force "tailored the report in order to bolster their biased conclusions." Motivations are repeatedly impugned, and it is suggested that at least some members of the task force were essentially servants of the pharmaceutical industry.

To those who are interested in controversies in medicine or have a particular interest in the treatment of schizophrenia this volume may be of interest. It can be read intelligently only by someone familiar with the literature and the task force report. Admittedly, megavitamin therapy has not been refuted because it is not scientifically possible to do so. One can only fail to show a value, one cannot demonstrate a lack of value. Clinicians must make up their minds on the basis of available evidence as to the most appropriate way of treating their patients. In a heterogeneous disorder such as schizophrenia there may well be a subgroup of patients for whom this approach will be useful. It would be of particular interest to know if this hypothetical group represents a fraction of a percent or is substantial in size. Such questions cannot be addressed in the present climate of charge and countercharge.

Competent and conscientious people have designed studies that failed to show a value to megavitamin therapy. Other colleagues who are equally competent and conscientious have reported studies that show positive results. Most workers in the field have concluded that the data do not support the use of megavitamin therapy except as an experimental technique. This position can be rejected by referring to its proponents as members of the Establishment. Equally pointless criticism can be made of those who support the use of megavitamin therapy. I hope that practitioners will have enough good sense to be guided by the facts rather than by the cleverness of the barbs. The major conclusion that can be drawn from this whole sorry controversy is that science is indeed a fragile activity that is most sensitive to injury by intense affect and certain human motivations.

Readings in Psychotherapy with Older People, *edited by Steven Steury, M.D., and Marie L. Blank, M.S.W. Rockville, Md., National Institute of Mental Health, Division of Special Mental Health Programs, Center for Studies of the Mental Health of the Aging, 1977, 233 pp., no price listed (paper).*

The editors of this work modestly state that their book is "offered as support and encouragement to therapists working with the elderly." What they deliver is a book that injects much-needed optimism into geriatric psychotherapy. In the preface to this compilation, Dr. Gene Cohen says, "The topic of aging generally stimulates much discussion about the need for breakthroughs in knowledge and techniques. However, we already know a great deal about . . . older people." He goes on to describe the need for information to be assembled to facilitate application of expertise that can alleviate much of the mental suffering of older people. This charge sets the tenor of the book, which focuses on the dynamics of aging and psychotherapy for the elderly within a historical framework.

The book contains papers by 26 contributors, 21 of whom are physicians. The papers fall into three broad categories: psychodynamics of aging, issues in psychotherapy for the elderly, and psychotherapeutic techniques. Each paper has been previously published, so for the reader familiar with the

literature this work provides a pleasant review and for the neophyte there will be new insights and useful suggestions of where to begin in therapy. The book would have been strengthened if the papers had been organized into a format with a clearer purpose and providing more depth to the material.

The papers chosen for this book uniformly reflect genuine optimism and enthusiasm for geriatric psychotherapy as well as warmth toward older people. These attitudes require much insight, training, and experience on the part of geriatric psychotherapists. These qualities are unquestionably possessed by the contributors to this work. The authors skillfully achieve their purpose of sensitizing therapists to the needs of the elderly and to the huge and frequently unrecognized potential of psychotherapy for the elderly.

Although there is little material in the book that can be readily applied by therapists who are not already knowledgeable in the field of aging and experienced in psychotherapy, there is a richness of information in this readable and rather short publication that could be of considerable value to therapists of all backgrounds who work with the elderly. This publication will probably become a standard reference in recommended reading for programs designed to teach or provide therapy for older people. Its primary purpose and value is in providing an honest, sensitive, and concise account of aging and selected issues in therapy. In doing this, the editors make a timely, implicit case for less pessimism and more psychotherapy in treating old persons.

Mind Control, *by Peter Schrag. New York, N.Y., Pantheon Books, 1978, 317 pp., $10.00.*

Mind Control is a lesson in polemics and a handbook for the antipsychiatry movement. If one accepts the definition of "hatchet job" as a maliciously destructive critique, we have an excellent example in this book. A master of hyperbole, Schrag cleverly selects the unusual dramatic event. Stopping just short of accusation, he cites an incident in a manner that suggests the purpose was nefarious and the episode typical. He is a master of guilt by association. Newspaper articles are cited as equal in evidence to scientific publications in refereed journals. Sixty pages of footnotes are arranged to suggest a careful scientific investigation.

In this book the culprits who would control your mind are psychiatrists and other mental health types. The scenario begins with a multitude of psychiatric labels and cleverly suggests that they could be applied to you and me and anyone. It moves on to the fears that computers and data banks engender. With such instruments readily available, the secrets in one's dossier are available to anyone at the punch of a button. It paints the picture of clever forces used to control individuals by subtle behavioral modification. The right combination of reinforcement will soon achieve the response desired. If that does not work, aversive methods will teach you not to do something as effectively as conditioning will promote positive action.

Schrag claims that there are more mental health workers in America than policemen. That is an interesting comparison. The mental health empire he describes achieves the "outreach of an octopus," developing liaison with schools, law enforcement, and all manner of agencies, all of it "backed by extensive advertising." If this is not enough, the acknowledged overuse of medication becomes even more frightening when one suggests that it is standard procedure for physicians to sign pads of blank prescriptions for others to dispense medications. The injectible forms of medication offer even more intriguing possibilities since their effects last for weeks. Schrag suggests that "if one can inject the recalcitrant . . . there will be no need to put Thorazine in drinking water." Here is a classic example of his technique, since the statement that chlorpromazine (Thorazine) will not have to be added to drinking water suggests that there was serious thought to do so.

Labels, psychological stimulation, and drugs are only the beginning. Schrag then points to the possibility of involuntary hospitalization. He suggests that the judicial hearing is a quick and cozy exercise based on a 10-minute psychiatric evaluation and 1.6 minutes with the judge. Once the victim is hospitalized, the horrors of ECT and psychosurgery are available. The book hints that patients are threatened with ECT if they do not behave. This treatment "burns and blasts out the electrochemical brain data." As if this prospect were insufficiently frightening, the threat of permanent mind control through psychosurgery is cited. After all, the author states, "hospitals are full of examples of individuals who were mutilated or whose intellectual capacities were destroyed by the lobotomies of the forties and fifties." The prospect becomes more vivid as he cites the only (to my knowledge) report of ECT behavior control from a project in Viet Nam, or a proposal made by one person to screen 8-year-old children for delinquent tendencies and incarcerate hard-core individuals. He further suggests that electrodes implanted in the brain could permit remote control of behavior. The problem is that this is not presented as science fiction and will be read by many as evidence of the real intent and professional activities of all psychiatrists. The technique is that mentioned in the first paragraph—clever use of a single unusual incident to suggest that it will become the standard for all psychiatric practice.

What does Schrag propose to do about the problems that psychiatrists call mental illness? He suggests that there would be no such problems if we had full employment and a shift of resources from therapy and "medical" interventions to the improvement of the social conditions that caused the problem in the first place. He insists that any psychiatric intervention be limited to serious cases (whatever they may be). He proposes that the symptoms of psychosis are simply idiosyncratic behavior or diversity of belief and that we should tolerate them as differences and not as deviance. He suggests absolute prohibition of treatment for unwilling individuals and elimination of any commitment laws. Public funds should be removed from the control of doctors and institutions to the control of "clients," who can then choose whether to use them for formal therapy, housing, or "simply a month at the beach which is likely to be at least as therapeutic as a month in the state asylum."

Lest the reader dismiss this book as "far out" or unusual, he or she should be reminded that similar arguments resulted in the passage of legislation that seriously restricted the use of ECT (even for voluntary patients) in California and other states. There has been a spate of proposals that mental illness is but a myth. Television programs suggest that psychiatrists use their patients sexually or incarcerate them unjustly. The patient suffering from mental disorder is hampered by stigma and prejudice against mental illness. The psychiatrist is pointed at as the opponent of freedom of thought and the proponent of mind control by a variety of evil schemes. Psychiatrists ought to read this book as a mat-

ter of education. Get to know what is said about you. It is no wonder that Mrs. Carter and the President's Commission on Mental Health have pointed to the goal of public education as a major requirement for an effective program for dealing with mental illness.

DONALD G. LANGSLEY, M.D.
Cincinnati, Ohio

The Mental Health Industry: A Cultural Phenomenon, *by Peter A. Magaro, Robert Gripp, and David J. McDowell, with the assistance of Ivan W. Miller III. New York, N.Y., Wiley-Interscience (John Wiley & Sons), 1978, 259 pp., $17.95.*

This is at once a highly disciplined book and a highly imaginative one; in neither dimension is the adjective used pejoratively. The authors are also ambitious in that they set out to cover a number of profound concepts, introduce detailed proofs of each thesis, and still add daring new ideas aimed toward solving the troubles they identify. The book is about many things, each intertwined with the others.

The authors briefly present the perspective that what we recognize as madness is sorely dependent on cultural conceptions. The idea that social expectations and demands define the deviant as mad is repeated more times than are examples offered to illustrate. Most readers can interpolate, however, and the bibliographical leads are excellent.

The text then turns unexpectedly but on second thought appropriately to a very precise discussion of two modern ideas of treatment for mental disease, milieu therapy and behavior modification. An excellent technical review of research data in both fields illustrates how inept most such research is when measured by actual effectiveness for the individual. The authors show that most research amounts to a lifeless default of any attempt to assess effectiveness beyond lip service to the established mode of thinking about things psychiatric.

The middle section of the book describes a vivid and often (for me, at least) uncomfortably detailed view of the mental health industry as it exists in America today. The authors insist that they are not interested in attacking their colleagues but are merely describing the current scene from a cultural perspective. Like psychoanalytic interpretations offered out of the goodness of our hearts, this kind of benevolent gift is sometimes experienced by the recipient as if it were hostile. I suspect many readers will feel the same about this book.

The central idea is something like this: since cultural structures have created our treatment systems, both the theoretical and the institutional structures have become solidified in order to perpetuate their own beliefs. The individuals involved in this process could be mental health bureaucrats, behavior therapists, or psychoanalysts. Mental health professionals are thus ultimately totally invested in maintaining the status quo, immersing themselves in the more pleasant patients who fit their particular scheme and ignoring the rest. Researchers also fail to address the essential problems of treatment effectiveness, attending instead to tiny details of behavior variations so they can produce publishable papers to enhance their own status quo. The public, the body politic, and the practitioners do not demand effective research because it might introduce change into their small smug world.

The book's section on the personalities of the providers who stifle research and narrowly hold to theoretical or institutional fixtures is especially choice. My 35 years in psychology and psychiatry have not been so secure that I felt no discomfort in reading this part of the text. Of course, the authors are more accurate in helping me perceive the flaws of my peers than in reminding me of my own flaws. They arouse most unpleasant memories of bitter jurisdictional battles in which I have unhappily participated.

The authors then shift focus once again. Although still in the mainstream of mental health politics, they expound a possible solution for this complex problem. Using the example of the GI Bill of Rights, according to which vouchers were in effect issued to individuals who could then attend any approved and monitored school, the authors suggest a similar plan for psychiatric treatment. In this last part of their presentation they provide a great deal of specific information and quite specific recommendations to implement their thesis. Specific predictions are made as to the probable results of this shift of economic perspective.

The authors feel that if funds were available to the individual for therapy of mental problems the effect would be free choice of practitioners and sharply increased demands on practitioners for therapeutic results (as opposed to pleasing the mental health commissioner). These practitioners in turn would demand from psychologically oriented researchers more practical research. Reading this I suffered at the agonies that would come if such a path to the platonic ideal were followed, a point not missed by the authors. The idea of individual enterprise comes as no shock to a conservative midwesterner. In fact, it seems a most familiar if often maligned point of view. Interestingly, the authors themselves are even a little apologetic: "For those of us coming out of a liberal background, the encouragement of a treatment system based on the concept of free enterprise seems a bit paradoxical" (p. 216). This is just one paradox that will greet readers of this book.

If your mind is set and you are ensconced in a pattern of practice beyond change, do not bother to read this book. You will only include the authors with other nonbelievers. If you are able, although perhaps not eager, to accept profound challenge as a researcher, practitioner, consumer, or part of the body politic, then read this book—not as gospel, of course, but as the provocateur it is.

RAYMOND HEADLEE, M.D.
Elm Grove, Wis.

Autistic Children: Teaching, Community and Research Approaches, *compiled and edited by Barbara Furneaux and Brian Roberts. Boston, Mass., Routledge & Kegan Paul, 1977, 193 pp., $12.00.*

One gets the distinct impression from the beginning of this book that there is still some controversy over the causation, diagnosis, and management of infantile autism, or Kanner's syndrome. This book promulgates the view that education is the most important factor in the management and treatment of the autistic child, along with active involvement of the parents in the care of the child, which is in direct opposition to Bruno Bettelheim's idea of rigid exclusion of the parents from the entire process of management, especially from the therapy of the autistic child. The authors stress that "the condition of the autistic child is not static nor are they a homogeneous group" and that no one type of professional can successfully deal with all the aspects of what they term the "autistic condition."

Brian Roberts' description of the conditions of autism and theories of causation in chapter two is instructive. Roberts examines closely Kanner's behavior criteria and some of Eisenberg's work and discusses the causation theories of Deslauriers and Carlson, which he feels to be most promising. In chapter three Furneaux talks at length about differential diagnosis and distinguishes among autism, childhood psychosis, childhood schizophrenia, and subnormal children. She lists the clues that the teacher can observe in a child's responses for the purpose of diagnosis: 1) Does the child respond? 2) How complete is his or her response? 3) Is his or her response appropriate or bizarre? 4) What is the normal speed of his or her responses? 5) Has the child the ability to follow through his or her responses in an appropriate manner? 6) Can he or she go from one thing to another when responding? 7) How well and for how long does he or she retain information? 8) Can he or she apply the information to a new set of circumstances? One phenomenon noted by some teachers is that an autistic child gives a bizarre response, but a subnormal child gives a slow response.

In chapter five Furneaux continues to stress the importance of the teacher in beginning the educational process for the autistic child. The teacher must define objectives and decide on an approach on the basis of considerations of the personality of the child and the extent of the child's remoteness and must constantly reevaluate methods for effectiveness according to the response of the child. The author seems to feel that the teacher can often successfully "lead from behind" and get the child going in a positive direction by means of close observation and patient attention to the child's individuality.

In chapter seven, which deals with research and teaching of autistic children, no clear methodology is outlined. Approaches to teaching include use of psychodynamic techniques, in which success is difficult to measure, and behavior techniques, which are easily measured but are difficult to duplicate outside the prescribed setting. The authors of this chapter note the common failure of behavioral techniques acquired in one situation. They conclude, however, that "not enough research has been done to enable the decision to be made as to which of the available approaches to the treatment and education of autistic children—the psychodynamic approach, behavior modification, or the use of a structured environment—has the most to recommend it."

This book gives a good basic understanding of the complexity of autism and how to differentiate it from other conditions. It tells succinctly what is being done currently in therapeutics and in education and what research is being contemplated. The authors are careful to document all their findings with a great deal of actual clinical material. It is worth reading and will make a good basic reference book, especially for teachers and for others helping in the care of autistic children.

PETER P. REILLY, M.D.
Providence, R.I.

Clinical Aspects of the Rapist, *edited by Richard T. Rada, M.D. New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1978, 225 pp., $15.50.*

This latest book in the Seminars in Psychiatry series is a timely as well as an important contribution to the professional literature on sexual assault. In the past five years there has been a dramatic increase in the number of publications on rape with a primary focus on the victim. As Rada points out, interest in the rapist has been confined to media coverage of sensational sex crimes committed rather than any consistent and systematic pursuit of the subject. The women's movement is credited with raising society's consciousness to the many factors of the problem. Now that the mental health, social service, law enforcement, medicine, and justice systems are aware of the increased reporting of the crime, the issues of prevention and control of rape are especially salient. There is a definite need to understand the offense, the offender, and the victim.

The focus of the book is on the rapist, defined as an adult male who sexually aggresses against an adult female. The strength of the book is in its multidisciplinary approach. Issues raised regarding the rapist are dealt with from many viewpoints. The stated purpose of the book is to present under one cover previous knowledge and new developments in the biology, psychology, sociology, and treatment of the rapist. This goal is accomplished.

The book begins with Rada's historical survey of the sexual psychopathy literature, starting with Krafft-Ebing's 1886 publication and continuing with writings from Freud, Ellis, Abraham, Ferenczi, and Stekel. The American literature began with Karpman's publication concerning a case of obscene letter writing in 1923 and expanded to include major works by Karpman, Gebhard, MacDonald, and Fain. A review of the key concepts in sexual psychopathy—perversion and sadism—includes a discussion of current trends in ego psychology as well as psychological conflicts over issues of power, control, and dominance.

One controversial issue among clinical researchers is the significance of sexuality in the commission of a rape. Rada cautions that we are still in the early phases of developing techniques to quantify sex drive and desire in rapists. A second equally controversial issue is the etiology of sex offenses. Various speculations have been offered and discussed: psychoanalytic theory (inordinate castration anxiety and acute oedipal conflicts caused by childhood witness experience), learning theory (first sexual experience as aversive experience reinforced through masturbation), egopsychology (interaction between conscious and unconscious attitudes of parents and subsequent attitudes and behavior of their children), psychodynamics (hostility toward authority figures), and sexual inadequacy (fear of sexual contact with women).

Following the introductory chapter is an in-depth discussion of biological, psychological, and social factors of the rapist. Rada is judicious to caution the reader not to assume that there is sufficient evidence to favor one point of view over another. This approach is quite refreshing given the amount of research in this field.

The psychological motivation for rape, according to Rada, is the desire for power, control, and dominance. The means for obtaining this control is the commission of the rape offense because sex represents to the rapist the best way to deprive a woman of her personal control. The differentiating factor in rape is the mode by which this control is effected (e.g., for some the manner of raping is sexual, for some it is primarily aggressive, for still others it is primarily humiliating). Rada describes the mode of raping on a continuum from sexual to aggressive with the middle point being sadistic.

An interesting conceptualization by Rada presents rape as a defense against feelings of sexual inadequacy, dependency needs, and homosexual wishes; rape as a displacement of hostility onto the victim; and rape as a symptom of a madon-

na-prostitute complex. Rada also reviews various psychological studies relative to early life experience of the rapist, intelligence and physical characteristics, dream material, sexual adequacy, marital relationships, and alcohol and drug use. The psychometric studies on sex offenders have many methodological problems. However, the studies are carefully reported and useful as background information, and some of the tests may be useful to the psychiatrist preparing diagnostic and disposition statements.

Contributions from sociology to the understanding of rape have until recently been derived primarily from criminology, a subdivision of sociology. It has been the emergence of the newer field of victimology that has prompted sociologists to focus attention on the subject. In an excellent chapter, Park Elliott Dietz lucidly summarizes the available literature on rape and sociological theories (crime as normal, anomie theory, differential opportunity, the delinquent subculture, role theory, and social learning theories). Dietz also reviews in detail empirical studies on rape and rapist behavior (variables of social status, race, and religion, pornography, temporal and spatial patterning, relationship between victim and offender, group rape, and cross-cultural perspectives). In a concluding section to his chapter Dietz introduces a thought-provoking area of injury control research that is a developing branch of public health. A schema is presented to depict the rape countermeasures (offender behavior, victim behavior, social and physical environment) designed to reduce the frequency or severity of injuries (by phases of prerape, rape, and postrape). Dietz advises that there be emphasis on social control of rape, believing that eradication of rape would require radical changes in our class structure, the social and spatial mobility of individuals, and the right to privacy. He states that rape is ineradicable and believes an important direction for future research is the reduction of frequency and severity of victim trauma.

There is a chapter on a classification system for rapists that Rada has found useful in clinical work and courtroom testimony. It focuses on descriptive psychiatric categories of the rapist and includes five different types: the psychotic rapist, the situational stress rapist, the masculine identity conflict rapist, the sadistic rapist, and the sociopathic rapist. Drawing from his research and literature review, Rada addresses biological aspects of the rapist (genetic neuroanatomical, neurophysiological, and psychoendocrinological factors) and organic methods used in treatment of the rapist (castration, psychosurgery, drugs, and ECT).

Chapter six, "An Integrated Treatment Program for Rapists," is essential reading for anyone interested in or currently treating rapists. This behaviorally oriented treatment model, designed and implemented by Abel, Blanchard, and Becker, introduces many new approaches in terms of research on rapists. The research project draws its sample from referrals and nonconvicted offenders, which counters the criticism that only convicted offenders are ever studied. This chapter helps to synthesize the abundance of material from the previous chapters. The clinicians identify five major areas of treatment: 1) establishing an empathetic relationship with the rapist, 2) confronting him with the fact that he is responsible for his rape behavior, 3) heterosocial-heterosexual skills training, 4) increasing arousal to adult women, and 5) decreasing arousal to the urge to rape. Detailed material from research and clinical practice is given for each of these areas, and the specific focus is on the techniques developed to reduce deviant sexual arousal (electrical aversion, covert sensitization, and chemical and olfactory aversion). The methods to develop heterosexual arousal (aversion relief, systematic desensitization, social retraining, classical conditioning, fading, and masturbatory conditioning) are also described. Most helpful are the case illustrations of the techniques developed.

The last chapter, on legal issues, is a dramatic departure from the style and content of the preceding chapters. Until this point, the chapters are clear, concise, and extremely well documented. Suddenly in chapter seven, the reader is told that one of the roles of the psychiatrist may be to determine the veracity of the victim's character. Attention then shifts to the concept of consent and corroborating evidence laws (including Wigmore's 1970 statement that the judge should ensure that a qualified physician take a social history of the victim and conduct a mental examination). Sadoff states that the psychiatrist should render an opinion as to whether the victim is fabricating the rape, covering up for her sexual conduct, or fantasizing the rape. The title of chapter seven is "The Psychiatrist and the Rapist," but no guidelines are given as to the types of questions or assessment the psychiatrist might follow in determining the rapist's mental state and the impact of his social and sexual history or fantasy life. If Sadoff wished to address issues relating to rape, he might have cited some of the aftermath symptoms that are useful in documenting trauma and that might help in preparing testimony for either prosecution or defense. To compensate for this chapter, I would refer readers to Elaine Hilberman's book (1) for a sensitive and well-documented account of victim trauma and legal issues.

This book is a major source of the current state of knowledge in regard to men who sexually assault women. Rada and associates have written a carefully documented book and have made an important beginning in addressing this issue from a clinical perspective. Because it is not the final word, several research questions need to be asked: What are the biopsychosocial aspects of sadism? What is the impact on children who witness sexual as well as aggressive activity? Why is rape the symptom-choice? How early can rape behavior begin? When can it be detected and how can it be treated? If rape control is to be a pragmatic concept, what research can the mental health fields bring to bear on this problem? In summary, this book is a basic text containing a wealth of information about the complex and multidetermined nature of forcible sexual assault.

ANN WOLBERT BURGESS, R.N., D.N.SC.
Chestnut Hill, Mass.

Current Psychiatric Therapies, Vol. 17, 1977, *edited by Jules H. Masserman, M.D. New York, N.Y., Grune & Stratton, 1977, 337 pp., $32.50.*

This series has held up well as a result of the energy and scholarship of the editor and the wide interests represented by the contributors. Volume 17 contains 11 sections covering administrative problems, the problems of childhood and adolescence, dyadic and group psychotherapies, psychopharmacology, alcoholism, various psychophysiological therapies, institutional problems, and some cultural considerations.

Gibson's essay on the rights of staff is a refreshing start. This chapter is especially reassuring to those of us who have

felt impaled on the horns of such therapeutic dilemmas as the patient's rights to have treatment and to refuse treatment. At least we have one voice raised in defense of psychiatrists' rights.

The editor contributes his usual introduction, in which he again demonstrates his facility with words and his preoccupation with them. After a whimsical beginning he provides a thoughtful and discerning discussion of the diagnostic and therapeutic problems that complicate our lives, opting for a reasonable return to common sense in both areas. Seymour Pollack's chapter, "Psychiatric-Legal Problems of Office Practice," is in this commonsense vein and should be required reading for every resident in psychiatry. I was especially impressed by Pollack's insistence that modifying diagnoses in order to effect certain social results is a questionable practice; the inevitable end-product of this must be a pervading distrust in diagnosis and diagnostician.

An interesting variant from the usual approach to such matters is Leonard Woodcock's address, "Psychiatric Treatment in Tommorrow's Health Care System." Since the United Auto Workers (UAW) has been a pioneer in the field of obtaining adequate insurance coverage for mental illness, it is fitting that Mr. Woodcock, former president of UAW, be chosen to discuss this topic; he does it well.

The section on childhood and adolescence includes chapters by Cohen on "Minimal Brain Dysfunction," White on "Psychotropic Drugs in Child and Adolescent Psychiatry," and Nadelson and Notman on "Treatment of the Pregnant Teenager and the Putative Father." The lattermost is a topic that might have had little significance a few years ago, but the authors point out that the reported incidence of coitus before the age of 15 has risen from 3% for girls in 1953 to 19% in 1973, with a concomitant increase in medical, social, and psychiatric problems.

In the section on dyadic psychotherapies there is less concern than in previous years with psychodynamics and more with the practical aspects of the therapeutic process, the importance of medical orientation (by Forsythe and associates), planned interruptions in psychotherapy (by Mendel), and the treatment of the chronic patient (by Mendel and Allen). Sayre provides a cautious and informative review of contemporary radical therapies, with a word of warning that "pilgrims of self-discovery may find that there is nothing substantial to be discovered."

The authors of the chapters in the section on family and group therapies offer straightforward discussions of group therapy of the traumatic neuroses and schizophrenia. The inclusion of incest in this section is certainly appropriate in view of the far-reaching effects of this problem in the family and even in the surrounding social structure. Speck and Rueveni offer a case illustration of their social network intervention technique; I was impressed by the energy and salesmanship involved in achieving the cooperation and attendance of 60 participants not in the crisis family.

In the section on psychopharmacology there are papers on "Placebos in Psychiatric Therapy," "L-Tryptophan: An Effective Hypnotic" (an interesting new possibility), good reviews on "Tricyclic Antidepressants in Outpatient Therapy" and "Drugs and Depression: Dosage and Blood Level Monitoring," and an interesting argument for the development of a specialized affective disorder clinic under the title "The Lithium Clinic: A New Model for the Delivery of Psychiatric Services." Subspecialty clinics certainly have proven to be useful in other fields of medicine; it might be interesting to see if they could be equally useful in psychiatry.

The increasing concern over tardive dyskinesia is reflected in two chapters, one on its prevention and one on its treatment. The section on alcoholism offers a good overview of the problem by Ewing, a description of the use of a day hospital by Savitz and Kolodner, and some notes on disulfiram by Rainey.

In the section on psychophysiological therapies are found discussions of such interesting new developments as autoacupressure and multiple-monitored ECT. The final chapter is a comprehensive review of the history and present status of psychosurgery. The author of this review is correctly critical of the lack of really objective evaluation of treatment results, pointing out that anecdotal reports of "improved functioning" and personal happiness are meaningless. The review is so comprehensive that it is a little surprising that no mention was made of Lindstorm's ultrasonic technique.

The section labeled Institutional is a delight to the pragmatic reader. One has a constantly recurring sense of déjà vu while reading Schwab's history of the evolution of a general hospital psychiatric unit. We have all lived through periods when the psychiatrist was seen as "unhappily removing from the medical system" and often having attitudes that were "harmful to the community." It is pleasant to note that after describing the intervening evolutionary process the author concludes that "psychiatric and medical diagnosis, rational psychosocial therapy and pharmacotherapy and aftercare planning are the significant features of our program." Treffert's plea for a sane asylum is both provocative and practical, although he admits that the name may have to be changed to be really accepted. Oberleder's directions for hospital staff care of the aging will be supportive and reassuring for nurses and others who are distressed by the slow progress and recurring problems found in this population.

In the final section, Itil and Reisberg raise some interesting questions about cultural differences in the prescription of and the patients' response to psychotropic medication. Of course, part of the difference could stem from cultural differences in expectations. Easson's discussion of orientation in psychiatric diagnosis and therapy in the Soviet Union contains some interesting and perhaps puzzling statements. For example, it is noted that most of the doctors in the Soviet Union are women, although "an increasing number of men is going into the medical profession." This is not surprising because it is also reported that most of the senior clinicians are men, and they make the final decisions.

The editor and contributors of this volume should be proud of this useful and informative product.

Second Thoughts: Selected Papers on Psychoanalysis, *by W.R. Bion, D.S.O., B.A. New York, N.Y., Jason Aronson 1977, 166 pp., $10.00.*

Dr. Bion is a renowned British psychoanalyst, clinician and theoretician who is teaching and practicing in Los Angeles. *Second Thoughts* is a collection of papers that were published between 1950 and 1962 and collected in one the present form with a final chapter of commentary—the second thoughts of the title.

Although these papers are mostly concerned with the psychoses, their scope is not limited to this topic, and no psychotherapist can disregard their importance to his or her work. Particularly is this true when they are read together with the commentary. Bion's skills in clinical observation,

his logic, and his original, illuminating points of view are worth the difficulties of confronting his closely packed and sometimes idiosyncratic style.

Bion's theoretical background is Kleinian, which will create a further intellectual hurdle for some readers, but again, one that will repay the effort. I acknowledge that much of Kleinian theory is confused and unconvincing for me. David Rapaport (1) stated baldly that the so-called theory of object relations of this school was an "id mythology." Nevertheless, the Kleinians number among themselves an astonishingly large group of outstanding clinicians. I have long puzzled over this fact and have concluded, tentatively and nonpejoratively, that the Klein school probably does not mysteriously and ab-initio attract for training great numbers of potentially outstanding clinicians; rather, the openness and proximity to fantasy of much of their theory permits and even assists greater access to primary process and to empathic perceptiveness of the psychic events within the patient and between patient and analyst.

Notable examples of this clinical perceptiveness occur in Bion's papers "On Arrogance" and "Attacks on Linking." One of the difficulties that psychoanalysis has had in promulgating its views is that, as Bion points out, it deals with experiences that are not available through the senses. Anxiety, for instance, is devoid of shape, size, color, or smell; the fact that the anxious patient may flush or sweat does not discredit this statement. One comes to understand the basic data of the patient, including what is verbalized by him or her and conceptualized from his or her associations by the analyst, by means of the empathized and cognitive effects that are internalized and integrated by the analyst.

It is largely true that the analyst knows his or her patient by means of what the analyst perceives and knows of his or her own internal and internalized processes as they operate in parallel with those of the patient. To tolerate in this way the stresses of the patient, to contain the patient's split-off intolerables and to remain balanced, would seem to be an occasion for the patient to feel gratitude. On the contrary, it is often the occasion for envy and hatred in the heated regression of the transference. Many therapeutic endeavors, analytic and otherwise, founder on the misunderstanding of this fact.

In "On Arrogance" Bion writes of certain patients whose analyses demonstrate "references to curiosity, arrogance and stupidity which are so dispersed and separated from each other that their relatedness may escape detection" (p. 86). He recognizes that this points to a past psychic "disaster" and to its imminent repetition in the transference through the failure of the analyst to "contain" and be a receptacle for the patient's projective identifications. I cannot summarize this further within the limited space of a book review; it is a brilliantly evocative and useful paper, deserving of clinical study and testing.

There will always be individuals who either fail to recognize that much of human experience is not reducible to physical facts or, if they do acknowledge an area of "the psychic," will deny that it is susceptible to scientific study. In recent years there has in addition been an unfortunate tendency to polarize so-called humanistic and scientific approaches to the study and treatment of mental ills. Often, such polarization has existed more in the minds of the polemicists than in the external facts. Bion's discussions of psychoanalytic patient-centered, humanistic treatment may help in dispelling the notion that psychoanalysis and humanism are incompatible.

Bion reconfirms in these and other writings the psychoanalytic employment of "freely hovering attention" and says much more that is useful about how the analyst works. He refers to the sharpening of intuition by means of the exclusion of "memory and desire" in the analyst's operations. Curiously and interestingly, he comments in this context on how the gap is to be bridged between reading the papers in this book and the psychoanalytical experience: "My suggestion is that the papers should be read in the same conditions as those in which a psycho-analysis should be conducted—without memory or desire. And then forgotten. They can be re-read; but *not* remembered" (p. 163; his italics).

This is not an expression of eccentricity; it is an operational statement that is courageous and useful. It also illustrates through the difficulties inherent in its execution some of the problems in applying the science of psychoanalysis and in teaching the finest state of its art.

Research on Smoking Behavior. NIDA Research Monograph 17, *edited by Murray E. Jarvik, M.D., Ph.D., Joseph W. Cullen, Ph.D., Ellen R. Gritz, Ph.D., Thomas M. Vogt, M.D., M.P.H., and Louis Jolyon West, M.D. Rockville, Md., National Institute on Drug Abuse, 1977, 377 pp., no price listed.*

This book is a compendium of papers presented at a conference on smoking behavior held in Los Angeles in June 1977. It upholds the high quality of previous publications in the NIDA Research Monograph series. Although there is a certain amount of repetition and rather loose organization, the editing is generally excellent, and what is repeated is of such consequence that it deserves to be reinforced.

The content is concerned with the fundamental aspects of tobacco smoking, which, with alcohol abuse, can be viewed as the most dangerous form of addictive behavior that society must contend with. Interestingly and perhaps significantly, both these substances are legal, easily available, and persistently and cunningly advertised (pushed).

The book is conveniently divided into four sections: Epidemiology, Etiology, Consequences, and Treatment. Each of these contains papers of extremely high caliber as well as useful discussion and session overview chapters. Taken together they provide a comprehensive account of the distribution and patterns of smoking behavior, biopsychosocial variables underlying the tobacco use syndrome, tobacco-related diseases, and prevention and treatment issues.

In spite of the attention given to smoking since Wynder and Graham's 1950 report linking tobacco smoking, especially cigarettes, with the induction of bronchiogenic carcinoma, there has been a stubborn persistence of the smoking habit. Leonard Schuman describes some important trends in the patterns of smoking in the United States, showing a gratifying but disappointingly modest decline in recent years. Of great concern is the fact that women have shown far less prominent declines in cigarette smoking than have men, and teenage girls show a continuous increase in smoking behavior. Also, both males and females are initiating their smoking

habit at earlier ages. This does not augur well for the future and emphasizes the Sisyphean nature of the task of preventing this addiction.

The reasons why people smoke remain unclear, and the etiology section serves to highlight the multifactorial nature of the dependency, as is the case in other addictive behaviors. Murray Jarvik makes a strong case for the central role of nicotine in cigarette smoking, and Dorothy Green reviews the factors that have been identified as contributing to cigarette use. Obviously, there are many of these, found in varying combinations in individual smokers, but pleasurable relaxation, stimulation, reduction of negative feelings, craving or psychological dependency, and simply habit play major roles. The fact that smoking rates are highest among divorced or separated individuals is a good example of the complex interaction between sociological and psychological factors in contributing to addictive behavior. Jerome Jaffe develops a very persuasive case for viewing dependence on tobacco in some individuals as being the same kind of phenomenon as dependence on other drugs. Tobacco use disorder will be a welcome and justified inclusion in the next edition of the American Psychiatric Association's *Diagnostic and Statistical Manual (DSM-III)*.

The treatment section includes a report by Jerome Schwartz on the various techniques used to help people to stop smoking and a discussion of the critically important issue of prevention by Ellen Gritz. As with the other sections the authors must be given the highest credit for excellent reviews of the current status of these complicated problems.

This book is a scholarly contribution to the understanding of a serious public health problem. It will be of value to a broad spectrum of readers.

ERIC W. FINE, M.D.
Wyncote, Pa.

Child Effects on Adults, *by Richard Q. Bell and Lawrence V. Harper. Hillsdale, N.J., Lawrence Erlbaum Associates (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1977, 236 pp., $12.95.*

This book, by two research psychologists (with a single additional contribution by a historian, Valerie French), is a collection of essays united by the theme that research and theory in developmental psychology has overemphasized a unidirectional model of interaction in which children's behavior is determined by the activities of the parents. The authors believe that this misguided emphasis has resulted in a failure to appreciate all the ways in which the behavior of adults is shaped by the activities of their children. The authors set about to overcome this error by a systematic review and reinterpretation of the literature in human and animal developmental psychology. Their method is to single out the child's effects on the parent or teacher in these studies. The goal is evidently to convince the reader of a model of developmental psychology based on constantly advancing reciprocal interactions between child and adult.

The book appears to be intended for the academic psychologist rather than the pediatric or mental health clinician. To judge from the labored and polemical style in which the authors express themselves, they apparently believe their thesis will face formidable opposition. However, the child psychiatrist or developmentally oriented clinician will find the constant repetition irritating and unnecessary. For the clinician, the concept of a finely tuned, constantly advancing reciprocal pattern of interaction between parent and child in which parents as well as their offspring develop and change is hardly novel. Clinical research in this area and its application to clinical work with children and their families has undergone great advances in the past decade or two.

The individual essays vary widely in quality. The first two chapters, devoted to enumerating attitudes toward children in Western history from ancient civilization to modern times, seem simplistic and irrelevant. This is unfortunate because several later chapters are well worth reading.

Chapters four, five, and six by Richard Bell are of particular interest. I recommend them to any student or clinician working with children. Chapter four begins with a concise review of the major studies of socialization. Bell then proposes a general explanatory model of mutual control systems by which mothers and infants regulate the upper and lower limits of their interactive behavior. This model takes into account the significance of congenital differences between children and the effect of environment and social stress on the responsiveness of the mother to the child.

Chapter five is a lucid presentation of research strategies in the field and their various advantages and disadvantages. It should be read by all who are interested in child developmental research. In chapter six, Bell presents his own formulation of the important developmental issues in the first year of life. He delineates four principal lines of development: 1) from activity to reactivity, 2) from preformed organization to malleability, 3) from stimulus reduction to stimulus seeking, and 4) proximal-distal shift. These lines of development occur within the matrix of three principal systems of mother/infant interaction: the behavioral interaction system, the caregiving interaction, and the social interaction. This developmental scheme is integrated with the research findings of Emde and associates' *Emotional Expression in Infancy* (1). I found Bell's formulations here reminiscent in some to Anna Freud's concept of developmental lines although more behaviorally oriented.

Chapters seven through eleven are by Harper. They are offered as supportive data to the major formulations of Bell and are useful principally because they pull together research findings from both animal and human studies in a concise and readable fashion.

In summary, this book contains a few chapters by Richard Bell that are pearls and deserve wide attention. As a whole, however, it is curiously ungainly and overpolemical. It is further marred by two clumsy, unnecessary introductory chapters of historical review that are likely to dissuade many readers from continuing before reaching the truly substantive parts of the book.

Dying and Death: A Clinical Guide for Caregivers *edited by David Barton, M.D. Baltimore, Md., Williams & Wilkins Co., 1977, 238 pp., $14.95 (paper).*

We see in our society unmistakable signs of a changing attitude toward death and dying. Widespread media cov-

erage of the topic and extensive course offerings at all levels bespeak a renewed interest in the subject and call our attention to the greater frankness with which matters relating to death are being discussed. Within the medical sphere these changes are perhaps most evident. In addition to a burgeoning literature there are signs of more open communication between dying patients and their physicians. The growing application of the hospice concept with its special programs for dying persons is an expression of this new attitude.

Yet, almost inevitably, a counter reaction has begun to appear. Some feel that little is being written about thanatology that is new or of substance. Others react negatively to the sentimental appeal or expression of romanticism of some writers and lecturers. A few physicians and nurses bristle at the urging of thanatologists to leave traditional roles in order to meet the needs of dying persons. Important shifts in attitude have occurred, but they are in danger of being undermined. One hopes that the passage of time will bring research efforts that support or refute present notions and increase the scientific respectability of the field.

In this climate new books continue to appear on the care of dying patients. *Dying and Death* is intended for all who have contact with such patients and will serve them well. The first half, written by Dr. Barton, covers the subject systematically. The second half includes chapters by different authors approaching it from a number of perspectives. Discussions by dying patients, an ethicist, a physician, and a clergyman reflect both personal experience and thoughtful consideration of the subject. Although somewhat obscure at points, Dr. Barton's writing also shows the influence of experience in dealing with individuals in the crisis of dying. He provides an in-depth review of major concepts and, despite little new material, an excellent statement of current thinking.

RUSSELL NOYES, M.D.

Biological Bases of Psychiatric Disorders, *edited by Alan Frazer, Ph.D., and Andrew Winokur, M.D., Ph.D. New York, N.Y., SP Books (Spectrum Publications), 1977, 262 pp., $15.00.*

Recent developments in our understanding of the biological bases of mental illness have been primarily in the correlates of the functional psychoses. It has been suggested that schizophrenic patients have raised serum creatine phosphokinase, raised autoimmunity, lowered platelet monoamine oxidase, raised histamine tolerance, raised CNS dopamine, and increased transmethylation. In the affective psychoses, biological theories include abnormal levels of biogenic amines, biogenic amine biosynthesis blocking studies, administration of monoamine precursors, and neuroendocrine changes. In addition, the drugs used to treat these illnesses have also been examined for what light they can shed on the biological correlates of mental illness. It has been suggested that phenothiazines block dopamine, that tricyclic antidepressants block the reuptake of noradrenaline, and that lithium impairs central catecholamine transmission. The benzodiazepines were also theorized to decrease the turnover of both norepinephrine and serotonin and to be related to the γ-aminobutyric acid (GABA) functions.

Although the genetics of alcoholism have been explored in the psychiatric literature, other biological correlates of propensities to alcoholism have usually been published elsewhere. Some workers have suggested that alcoholics have a lowered production of adversive acetaldehyde. Other investigators theorize an opiate-like substance as a metabolite of alcohol.

The editors of *Biological Bases of Psychiatric Disorders* are to be congratulated on their ability to maintain their central theme in many of the contributed chapters in this book. The findings listed above are discussed in brief, and frequent reference is made to literature sources. These theories and the experimental work related to them are exciting developments for psychiatrists interested in biological theories of etiology of various mental illnesses. Most of the chapters are appropriately restrained in their exposition of etiological relationships. The title of the book is perhaps less restrained than these chapters.

Of particular interest are the chapters on "Biological Theories of Schizophrenia" by Lipinski and Matthysse, "Biological Aspects of Mania and Depression" by Alan Frazer, "Alcoholism" by James Stinnett, and "Therapeutic and Pharmacological Aspects of Psychotropic Drugs" by Frazer and Winokur. Lipinski and Matthysse cite their more extensive chapter in the 1975 *Annual Review of Medicine* (1), but they do not emphasize this excellent reference to the extent that it deserves. This book is aimed at the introductory neuroscientist. It is more current and informative than many books with this aim.

Cleveland, Ohio

The Placebo Effect in Healing, *by Michael Jospe. Lexington, Mass., Lexington Books (D.C. Heath and Co.), 1978, 162 pp., $15.95.*

Long before Beecher (1) wrote about "the powerful placebo," healers had an awareness that not all patient response could be attributed to the direct actions of any particular potion, pill, or procedure. Indeed, the origin of the word "placebo," which means "I will please," indicates knowledge that a pleased patient may sometimes be equated with a responsive and recovering patient. For behavioral scientists the mechanism of placebo response remains a research challenge demanding theories that can be tested. Michael Jospe is a psychologist who has carefully reviewed the placebo literature and now presents an excellent and up-to-date overview that should be of value to all who are interested in the topic.

After offering a historical perspective, the author reviews laboratory experiments before proceeding to clinical situations. Of special interest are sections on the placebo effect in psychiatry and psychotherapy. A good deal is known about personality and habits of placebo reactors. For example, they are often churchgoers who depend on others and trust in the ability of others to help them.

An excellent chapter on methodological problems in placebo research leads to a final section in which the author draws a comparison between placebo response and Schachter's theory of emotion, which states, "When people are in a state of arousal, they may experience very disparate emo-

tional states or no emotional states at all, depending on the concurrent cognitions" (2). Jospe suggests that, according to such a view, the placebo effect can be interpreted as having three components: physiological arousal, emotionally relevant cognitive or situational factors, and a perceived causal link between these factors.

He concludes with a review of recent work in attribution research that has become an important part of social psychology. Jospe believes that further understanding of the placebo can come from conceiving factors in relation to attribution, from which a network of testable hypotheses could be produced.

Much work remains to be done in this area, but the present volume is a valuable contribution and I hope that the author will publish updating editions from time to time as knowledge advances.

The Annual of Psychoanalysis, Vol. V, *edited by the Chicago Institute for Psychoanalysis. New York, N.Y., International Universities Press, 1977, 436 pp., $17.50.*

This is the fifth volume of what might be called the *Fortune* magazine of psychoanalysis. It maintains its usual high caliber of articles. In the first section, Psychoanalytic History, George Pollock's very interesting "The Chicago Institute for Psychoanalysis from 1932 to the Present" includes the mention of the leading analysts of that day and of both the Berlin and Viennese Institutes. W.W. Meissner's "The Wolf Man and the Paranoid Process" is a carefully detailed analysis but so technically written as to be easily read only by those analysts versed in metapsychological thought processes. For example, Meissner states,

> One stratum of the introjective organization thus derived can be described in terms of the correlative pairing of victim-introject and aggressor-introject. Both of these elements could be identified in the father's introjective organization, but were undoubtedly made more complex and complemented by the integration of introjective components derived from the Wolf Man's mother.

In section two, Clinical Theory, Sklansky summarizes his "The Alchemy of Love" as follows: "The two major forms of libidinal experience, erotic and narcissistic, are confluent and synergistic throughout development, and are transmuted from coarse separate strands into the finer coalescence of young adult love." Arnold Goldberg's "Some Countertransference Phenomena in the Analysis of Perversions" stresses narcissistic elements, and Ira Miller's "On Sadness" continues this occupation with narcissistic elements. Pollock summarizes succinctly the history of Alexander's psychosomatic specificity concept as it developed from specificity of a disease to specificity of a human being. Selma Fraiberg brings to psychoanalytic studies of ego development rich observations on children with congenital sensory and motor defects, supplemented by Freedman's "Studies in Sensory Deprivation" in children. Donald Silver finds that contact lenses have unconscious significance for separation and defloration and many of the anxieties of the adolescent female.

In section three, Developmental Psychology, Essman's excellent and clearly written "Developmental Psychology and Explanatory Theory in Psychoanalysis" shows how Freudian and Piagetian psychologies complement each other, thus advancing the unification of psychology.

Section four, Clinical Psychoanalysis, opens with an illuminating "Preliminary Report of a Case of Consummated Mother-Son Incest" by M. Margolis. It is followed by "Comments on the General Functioning of the Analyst in the Psychoanalytic Situation" by Lichtenberg and Slap, a timely discussion of the suggestion that the analyst be humane and natural instead of a blank screen.

Section five is composed of Gedo's "Essay on Psychoanalytic Education." Gedo looks beyond mere quantitative improvements in the existing psychoanalytic institutes to transforming them into mini-universities where interested participants at all levels of experience can join for corrective learning.

Section six, Psychoanalysis and Psychotherapy, consists of Paul and Anna Ornstein's reflections and predictions "On the Continuing Evolution of Psychoanalytic Psychotherapy," with an excellent discussion by Zaleznik and Schwaber. This article falsely sees psychoanalytically oriented psychotherapy as not recognizing the process nature of psychotherapy, thereby being technique-oriented without guidelines for its intervention, but the authors are trying to develop a systematic theory of the psychoanalytic therapies.

In section seven, A Tribute, it is good to see "Reflections on the Occasion of Jean Piaget's Eightieth Birthday," by Heinz Kohut because it is a step in the unification of the best in all the psychologies.

Section eight, Application, contains Weisblatt's "The Creativity of Sylvia Plath's *Ariel* Period: Toward Origins and Meanings." The author sees as most important "the ultimately failing attempt at mastery of the regressively resonated traumatic state." W.W. Meissner follows with "A Case in Point," which illustrates the "paranoid process" in the case of Golyadkin, hero of Dostoevsky's *The Double*.

Happily, this year the quotations and case material are in normal-sized rather than overly small print. This avoids the previously irritating interruptions of the reader's concentration and adds to the enjoyment of this varied fare.

That Which Is: An Inquiry Into the Nature of Energy, Ethics, and Mental Health, *by John O. Beahrs, M.D. Palo Alto, Calif., Science and Behavior Books, 1977, 260 pp., $11.95.*

In the complexities and pressures of twentieth century living, while mankind is attempting to deal with a technology that threatens to overwhelm us all, the philosophical and religious concepts of past centuries are less satisfying to many. Ours is an age of skepticism on the one hand and a need for a philosophical home base that stands up under the penetrating scrutiny of today's scientific knowledge on the other.

The author, a young psychiatrist who practices in the northwest, addresses this problem in *That Which Is*. He believes that the philosophical answers he has formulated have practical applications for coping with much of the emotional and mental malaise seen by today's practicing psychiatrist.

Beahrs points to the philosophical dualism postulated by Descartes as the basic problem in reconciling dogmatic Western religious philosophy with scientific thinking. The error lies in viewing the material and spiritual aspects of existence as separate entities. Beahrs describes the thinking of Descartes as ontological dualism: "a belief in the existence of two entirely separate but equally real substances: 'Material,' constituting the material universe and our bodies, and 'Spiritual,' constituting God and our minds." The Christian church, according to Beahrs, is the bastion of ontological dualism in that it holds to the concept that God and man's spiritual nature are separate and apart from the material world—from the clay from which man was fashioned.

Beahrs declares philosophical war on religions based on ontological dualism. He terms these "religions of fantasy." In his quest for the true nature of reality, he prefers to turn to the monistic philosophy of Benedict de Spinoza and to bring up to date that seventeenth-century philosopher's pantheistic concepts in the light of modern physics and psychology. This book is dedicated to Spinoza.

The book is composed of four essays. The first discusses the irreconcilable contradictions of ontological dualism (viewing God, mind, thought, and moral concepts as spiritual and viewing objective reality as material). Through logic and theories of modern physics, the author presents his view of the true nature of existence, the basic principle of which is that all that has been experienced by human beings throughout history (physical matter, energy, life, feelings, intellect, divinity, and whatever else) is constituted of the same "stuff" or "substance" that is eternal, unbounded, and unchangeable in its basic nature. This substance is not "crude, inert, lifeless matter" as commonly conceived but is identical to pure energy as the term is used in physics.

Beahrs offers convincing scientific arguments that the molecular structures of all things in the universe have an ultimate common denominator—energy. Higher forms of life and brain function are simply more complex organizations of this omnipresent essence. Then, in a series of brilliantly expounded propositions, he makes a philosophical extension of his concept of energy essence to argue that energy is spiritual in the final analysis and that "spirituality is the essence of energy as it exists independently of an external observer." He terms his theory of energy "spiritual monism," summing it up by declaring, "All existence is constituted by one 'stuff'—energy—whose true essence is spiritual. It is regarded as 'material' only when viewed by an external observer."

The author proposes an interesting division of the polarities of consciousness, terming the conscious, reasoning level "Self 1," which is related to the left hemisphere of the brain, and the unconscious level "Self 2," related to the right hemisphere of the brain. Self 1 is the executive; it is voluntary, gives commands, and is linguistic, denotative, and digital. Self 2 is involuntary, spontaneous, symbolic, and analogic. Self 1 represents advanced or higher development. Self 2 represents primitive or lower development.

The author then goes a step farther and suggests a Self 3, a more primitive and basic level of human brain function, even more primitive than the Freudian Id. In a theological sense, this deep lower level of being is the system's support and power base, a level of biological function and a link with God and reality. Prayer, in the author's view, is perhaps a form of self-hypnosis that has a real and scientific application. In praying, one voluntarily surrenders his or her primary Self 1, surrenders himself or herself to "God's will," and thus reaches the deeper levels of his or her personality: "What is our link with God, with ultimate reality—That Which is—but the very deepest, most basic roots of our personality, first Self 2, then Self 3." This idea is not entirely unlike the thought of William James (1), who suggested that if man experiences God, it may be through subconscious levels of the mind.

In his personal preface to the book Beahrs recalls his own early adjustment difficulties in reconciling himself to the dualism of dogmatic religions. This personal factor no doubt strongly influenced both the writing and the direction of this book.

Review of Inhalants: Euphoria to Dysfunction. NIDA Research Monograph 15, *edited by Charles Wm. Sharp, Ph.D., and Mary Lee Brehm, Ph.D. Rockville, Md., National Institute on Drug Abuse, 1977, 345 pp., no price listed (paper).*

This monograph on inhalants and inhalant abuse, the outgrowth of a NIDA-sponsored conference held in June 1977, aims at providing "a thorough review of the literature and critical assessment of the state of our knowledge . . . and an important post-1970 selected bibliography on the topic." Its chapters outline the epidemiology of inhalants, psychological factors predisposing to use, mental status and personality studies of users, medical and neurological evaluation of inhalant abusers, and preclinical pharmacological, toxicological, and behavioral studies. In addition to the bibliography noted above, each of the chapters has its own excellent list of references. Although an excellent summary of current knowledge, the monograph highlights our lack of understanding. Unfortunately, it serves more to outline our confusion and to uncover poor methodology and ignorance than to illuminate.

The phenomenon of glue-sniffing commonly involves an unknown number of individuals from unknown populations who inhale a wide variety of volatile substances, often in unknown combinations. Exposure may in time (in some known cases, does) produce a series of undefined or ill-defined toxicities in addition to the subjective experience defined by the user as a high. The substances known to be used in this way, singly or in commercially available combinations (often with changing formulas), include aliphatic and aromatic hydrocarbons, halgenated hydrocarbons, freons, aliphatic nitrites, ketones, esters, alcohols, glycols, ethers, and gases. Many of these are easily available, conveniently packaged, and cheap (e.g., varnish, gasoline, and nail polish remover). Perhaps for these reasons such agents are often the first nonmedically used psychoactive agents, sometimes antedating alcohol and tobacco use. They appear to be used early and may serve as an introduction to other drug use. Usage is reported to decrease with age.

The youth of the prototype user, who is usually pre-

adolescent or in early adolescence, combined with possible subtle neurological deficits, may result in markedly dysfunctional adults. The search for obliteration of reality in place of adaptation often precludes maturation. Unfortunately, the data available do not permit firm conclusions. Despite this, a variety of controls have been suggested and in some areas instituted. These recommendations include the addition of noxious or unpleasant agents to substances of possible abuse and/or forbidding their sale to minors. The first may merely add to toxicity or drive users to more questionable compounds, and the second is unrealistic when one considers the number of preparations, their wide distribution, and their many uses in the home and commercially.

Remedies should be applied only when it is clear that there is a significant problem and when it is clear that the remedy is less dangerous than the disease. It is important that we not contribute to the harm people do to themselves. We need careful study, clinical as well as preclinical, behavioral as well as biological, to uncover the complex motivations of users and the physiology and pathophysiology of use. Intelligent intervention can only follow understanding. This volume clearly states the problem as well as charting the needed courses.

Transactional Analysis After Eric Berne: Teachings and Practices of Three TA Schools, *edited by Graham Barnes. New York, N.Y., Harper's College Press (Harper & Row), 1977, 531 pp., $15.95.*

The psychotherapeutic strategies known as transactional analysis (TA) began about 1955 when Eric Berne introduced the concepts of Parent, Adult, and Child ego states and enlarged on these ideas with transactions and games theories that were related to the communications theories of cybernetics (1). Both TA and Gestalt therapy, which overlap in theory and in practitioners, have roots in group therapy and often emphasize rapid change in symptomatic behavior. The International Transactional Analysis Association now has almost 10,000 members in 35 countries, according to the preface of this book.

Transactional Analysis After Eric Berne is a collection of 22 articles by leading TA practitioners and theorists. It is a very good sampling of the TA universe, showing how the concepts of the "classical school" (Parent, Adult, and Child life scripts) differ in emphasis from those of the "redecision school" (Robert and Mary Goulding's role playing and redeciding of self-defeating rules learned in childhood) and from those of the "cathexis school" (Jacqui Schiff's Ferenczi-like treatment, the reparenting of schizophrenic patients in a residential setting).

Therapists usually begin by teaching TA concepts to patients (chapter 22, "What Transactional Analysts Want Their Clients to Know" by Woollams, Brown, and Huige). The terminology of TA is apparently chosen to be meaningful to patients (e.g., "games," "rackets" and "racketeering," "sleepy, scary, and spunky forces," and "strokes"), Robert Goulding describes rapid treatment of phobias. Robert Drye describes "The Best of Two Worlds: A Psychoanalyst Looks at TA."

A number of the leaders in TA are psychiatrists and psychoanalysts, but there is little emphasis on precise diagnosis and few significant elements of an empirical or medical model in this book. Its major purpose is to give an overview of the complexity of theory and practice that has developed in the last decade and to be used as a textbook in teaching. It succeeds very well in these purposes. However, I can find no outcome data in this book other than case descriptions by an individual therapist and anecdotes, and there is no systematic attempt to evaluate the effectiveness of what I found many therapeutic strategies that make good sense. However, This is a stimulating book of ideas for the psychotherapist.

Beyond the Male Myth: What Women Want to Know About Men's Sexuality. A Nationwide Survey, *by Anthony Pietropinto, M.D., and Jacqueline Simenauer. New York, N.Y., Times Books, 1978, 417 pp., $12.50.*

Not since the 1948 Kinsey report has there been such a revealing look at the sexual and emotional preoccupations of today's American male. *Beyond the Male Myth* is mandatory reading for women of all ages who are concerned about their relationships with men. The authors, one a psychiatrist and the other a psychiatric editor and writer, asked women what they wanted to know about men because their sexual response is affected by the many myths and changing attitudes about male sexuality.

The statistics come out of a random sample of more than 4,000 men carefully controlled for age, education, income, occupation, race, and marital status. Age, race, education, and occupation were found to produce substantial differences in the findings. For example, 70% of the men under age 40 said they would cheat on their women, compared with 36% of the men over 55 years old. Of the younger group, 31% said they liked oral sex best compared with 16% of men over 40. Thirty percent of the high school graduates reported that sex was their greatest pleasure, but 17% of the college graduates reported this attitude. The biggest discrepancy on the basis of race came with attitudes relating to the overall importance of sex: 64% of the white respondents and 41% of the black respondents reported that sex was "not the most but a very important pleasure." Sixty-five percent of the college graduates reported that sex was very important, compared with 48% of those with less than a high school education. The choice of marriage with outside sexual activity climbed steadily in popularity with earning power: 12% of the men earning less than $10,000 would choose this option compared with 27% of those earning $27,000 or more. A greater percent of professional men would choose this option.

The authors' survey also destroys a number of myths. For example, 87% of the married men reported that they still believed that marriage was their best option; 2 out of 3 men expressed positive views about women's liberation, men reported that they were not preoccupied with youthful sexual partners; 4 out of 5 men said they made a conscious effort to delay orgasm; and 98% said they felt that it was important for a woman to have an orgasm and that love, companionship, and home life were more important than sex.

By comparing studies done by Kinsey, Hunt, Kaplan

Hite, and the Rubins, the authors note the changing attitudes of men toward women and their own sexuality. They describe such notables as Cleopatra, Hera, Don Juan, Farah Fawcett-Majors, Lucille Ball, and Mary Magdalene; such movies as *A Clockwork Orange, Catch-22,* and *Divorce, Italian Style;* and such plays as *Hair* and *The Divine Comedy* to break up the collage of figures that may otherwise confuse the reader. Pietropinto's interpretations, opinions, and case histories add a reflective touch that stimulates the reader's own thoughts.

On completion of this book, I find I have three main questions. Why is it that women complain of male insensitivity in the light of the fact that men see themselves as being highly sensitive? If marriage is the most desired option of men, why do they jeopardize it by being unfaithful? Finally, what is it about the nature of the marital relationship that it is so abused yet so sought after by men and women?

Morrisville, Pa.

Clinical and Experimental Hypnosis in Medicine, Dentistry, and Psychology, 2nd ed., *by William S. Kroger, M.D. Philadelphia, Pa., J.B. Lippincott Co., 1977, 391 pp., $21.00.*

The author has written a big book in which he attempts to cover the enormous field of clinical and experimental hypnosis in medicine, dentistry, and psychology. He is too ambitious in this venture. However, there are a few advantages for the reader.

The volume opens with basic themes that appear in most volumes on this subject. There are chapters covering the history of hypnosis, hypnotic phenomena, suggestion and suggestibility, theories, induction procedures, and misconceptions about hypnosis. There are data also on autohypnosis, group hypnosis, precautions and dangers, and dehypnotization. The author deals with additional subjects, not all of which are to be found in other books on hypnosis. He discusses antisocial aspects of hypnosis, legal and ethical issues, including criminal investigation, and religious concerns. He has material on magic and faith healing, placebo effects, biofeedback, meditation, semantics, learning theory, and behavior modification.

He then moves on to a vast territory, as a result of which one legitimately wonders how much ground an author is in a position to manage with his own measure of experience. Kroger deals with neurophysiological and psychophysiological mechanisms and presents material from an array of medical specialties and subspecialties. These encompass internal medicine, surgery and anesthesiology, obstetrics, gynecology, dermatology, physical rehabilitation, ophthalmology, otolaryngology and rhinology, genito-urinary problems, oncology, pediatrics, orthopedics, and dentistry (this contribution was prepared by a dentist colleague). He focuses, in addition, on acupuncture and a variety of miscellaneous problems and offers a comparative evaluation and criticism of hypnotherapy and psychoanalysis.

It was possible during the nineteenth century for one determined individual to be concerned with and to attempt to write about the entire field of medical and scientific hypnosis. There are several well-known classics of such literature. Both authors could still attempt this in the early decades of the twentieth century. Because of advances in medical specialization and growth of the field of psychology, however, no one person in the last few decades could possibly master all of these areas. It is for this reason that books have been written by several authors and edited with specialists in various areas contributing chapters based on their personal experience and knowledge.

However, Kroger's book can be helpful, especially to novices involved in clinical and experimental hypnosis who wish to search for some preliminary information in the areas of concern to them. They are in a position to seek out references supplied at the end of chapters for guidance toward additional reading in the works, books, and articles by investigators writing about their personal experience. In this book, some investigators are referred to by name as well as reference number in the text. There are numerous instances in which only reference numbers are supplied so that the reader does not know immediately which contributors are responsible for statements of fact, allegations, or opinions referred to in the text itself; it is necessary to turn to the reference list at the end of the appropriate chapter for such information. Consistent with this observation, one notes that the book has a subject index but not an author index.

Despite the shortcomings mentioned, the merits of the book permit recommending it to readers as an initial reference for preliminary information and as a guide to other writings for data based on direct experience of specialists in the many areas of clinical and experimental hypnosis.

New York, N.Y.

Should the Children Know? Encounters with Death in the Lives of Children, *by Marguerita Rudolph. New York, N.Y., Schocken Books, 1978, 110 pp., $8.95.*

Unfortunately, the title of this book promises more than can be found in its text. Initially I had a fantasy of reading an exhaustive clinical disquisition on the multifaceted aspects of death as it relates to children. I was unprepared, although not necessarily disappointed, to read a more limited, personalized, and anecdotal presentation on the subject.

The author provides "case" material gathered from her work as a teacher and director of preschool and day-care programs and from her personal experiences as a mother and grandmother. She displays the wisdom and sensitivity of a knowledgeable paraprofessional and offers some perceptive and absorbing glimpses of the older preschool child's reactions to the death of a classmate, a pet animal, or an aged great-grandmother. The children she describes are enmeshed in what Fraiberg (1) called the magic years. This is the time when fantasy, dreams, enchantment, and curiosity blend with and complement the dawning of an intellectual discrimination between magical thought and real experience. Thus, for the child, death is both a separation from a loved one and a nonpermanent but real state like sleep. This is reflected in the children's questions, which the author uses as chapter titles: "Does the World Stop? Who Deaded Him?" and "Can You Still Have a Birthday When You Die?"

There is an answer to the book's provocative title, *Should the Children Know?* By the process of psychologically working through the untimely death of a preschooler named Rachel, Ms. Rudulph answers affirmatively. She believes a child has the right to feel the sadness and grief inherent in working through feelings about death without the interference of a "protecting" adult who would say, "Tell them Rachel moved."

Aside from implying that Dr. Elisabeth Kübler-Ross is a

psychologist and that "in the Jewish tradition, children are named for dead relatives" (this is customary among Ashkenazim, but Sephardic Jews often share a child's name with that of a living relative [2]), this book is sensibly written, geared primarily for the lay reader or teacher, and includes a useful annotated bibliography for additional exploration of subjects relating to death-education for children.

The Meaning of Anxiety, revised ed., *by Rollo May. New York, N.Y., W.W. Norton & Co., 1977, 425 pp., $12.95.*

Dr. May is a training and supervising analyst at the William Alanson White Institute. He wrote the first version of this book in 1950. In this revised edition, he adds two new chapters on the management of anxiety.

The general aim of this work is to summarize the various theories of anxiety, which Dr. May describes as "a pervasive and profound phenomenon of the time we live in," appropriately called by Auden the Age of Anxiety. The interpretations of Spinoza, Pascal, Kierkegaard, Freud, Rank, Adler, Jung, Horney, Sullivan, and others are examined in an attempt to synthesize the various viewpoints into a comprehensive theory. To summarize such complex theories is an ambitious project indeed, and the reader is left with the uneasy impression that some synopses might suffer in objectivity and in depth. For example, one is struck by the importance that May gives to Freud's early formulations of anxiety, the ones that are certainly of less significance to the psychotherapist.

Although a full chapter is devoted to the biological interpretation of anxiety, no useful reference is made to its pharmacological management, as if the therapeutic means available to the clinician had remained at the stage they were in 25 years ago. In a brief footnote (page 262) the author describes how a young man he treated in psychotherapy ended up being lobotomized, and continues, "If drugs had been available when he was in the hospital, this would have been one time they would have been useful to tide him over that episode." This is hardly a comprehensive view of what drugs have to offer. It seems as if the author ignores or underestimates the important role played by anxiolytic and antipsychotic drugs in controlling the symptoms of anxiety found in various psychotic and neurotic conditions. The exclusively psychotherapeutic approach he suggests will be of limited value to the practicing psychiatrist. He also makes no mention of the use of relaxation and of deconditioning in the treatment of anxiety.

Dr. May seems convinced that anxiety is essential to the human condition in that it creates a tension necessary to preserve human existence and creativity. As true as this hypothesis might be from a philosophical standpoint, the fact remains that physicians have more to offer therapeutically to their patients than what is presented in the last two chapters of this book. The weakness of the new section might be due to the fact that the author's diagnostic distinction between psychologically crippling anxiety states and "normal anxiety" seems very vague.

Richard Chessick (1) stressed that "the psychotherapist, in order to become relatively wise and mature, must understand something about history, philosophy, ethics, philosophy of science, psychology, anthropology and sociology." Although *The Meaning of Anxiety* does not provide new theoretical or therapeutic insights, it can be recommended for humanistically inclined readers who do not have the time to go back to original sources.

Psychotherapy and Its Financial Feasibility Within the National Health Care System. Publication 100, *by the Group for the Advancement of Psychiatry Committee on Therapy. New York, N.Y., GAP, 1978, 45 pp., $2.50 (paper).*

This GAP publication is a well-written and concise statement of the case for including psychotherapy under national health insurance (NHI). It is written for the informed layman and for key policy planners. The writers are to be commended for their lack of jargon as well as their direct style.

This pamphlet presents its strongest argument for the value of psychotherapy from a humanitarian perspective. The authors articulate well the human pain associated with mental illness, especially neurotic illness, and the need for care of suffering human beings. The clinical examples presented are well drawn and persuasive. However, the arguments presented in terms of more hard-headed financial cost benefit issues are simplistic and unconvincing. This is especially true in the case for long-term intensive psychotherapy as contrasted to short-term psychotherapy.

Most policy planners and even some budget analysts concede that short-term psychotherapy is cost effective and are willing to consider the cost offsets in general medical utilization with short-term psychotherapy. The higher cost inherent in high intensity treatments such as psychoanalysis is another issue altogether. In addition to the higher cost there is the issue of the appropriateness of such care and the socioeconomic class and educational biases of patients who receive such care. The criteria and indications for long-term intensive psychotherapy are not well understood at the present time. This pamphlet implies that we have already developed diagnostic and prognostic criteria that could clearly delineate the most effective treatment for a given individual. Since these treatments vary in cost by as much as ten times, this is not an academic exercise.

Other basic problems in the case for coverage of long-term intensive psychotherapy involve the extent to which the treatment can be conceptualized as "medicine." In physical medicine the diseased organ and to a lesser extent the diseased person are the prime foci of intervention and insurance coverage. The long-term goals of intensive psychotherapy and psychoanalysis imply considerable efforts at re-education and as such do not conform well to the medical model.

In addition, the credentials of various professionals to perform the treatment and the lack of clear role specialization

create other economic problems as more nonpsychiatrist professionals claim expertise in performing this treatment. As these professionals are reimbursed by health insurance carriers as independent practitioners the utilization and costs go up. The issues of who can perform and who should be paid for this treatment are not addressed at all in this publication.

From the perspective of long-term intensive psychotherapy, it is essential that the West German studies cited in this publication be replicated in this country and that there be increased understanding on the part of insurance companies and policy planners as to the value of long-term intensive psychotherapy. With this understanding will come an increased willingness to finance such treatment.

It would have also been better to elaborate on the key equity issue of the appropriateness of long-term intensive psychotherapy for patients from lower socioeconomic groups. At present, long-term intensive psychotherapy is utilized almost exclusively by college-educated white people from the middle and upper classes. Would NHI coverage of long-term intensive psychotherapy be a subsidy of the rich by the poor? The equity issue of the redistribution of health resources to the poor and minority groups in the United States through national health insurance precludes consideration of this form of treatment unless it is considered utilizable by those for whom such care has been traditionally denied. We need more data on this issue.

Rockville, Md.

Emergency Psychotherapy and Brief Psychotherapy, 2nd ed., *by Leopold Bellak, M.D., and Leonard Small, Ph.D. New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1978, 274 pp., $18.50.*

This book, which was first published about 10 years ago, has been revised and expanded because of the growing interest in a subject whose importance has finally been recognized. It is composed of three parts. The first deals with basic principles and methods, the second lists several clinical syndromes illustrated with case examples, and the final one contains a discussion of a multiple-level study of brief psychotherapy in a clinic setting. Three case histories conclude the volume.

Valuable information is offered to the reader about various definitions, theories, and principles of brief psychotherapy, and a five-to-six-session therapy is described briefly. The discussions of diagnostic formulation, history taking, therapeutic contract and alliance, transference, interpretation, and termination issues are quite helpful.

One difficulty with the book, as far as I am concerned, has to do with the position taken by the authors in reference to planning psychotherapy "within the framework of what the patient is willing to engage in." This surrender to consumerism undermines the basic conclusion shared by several investigators in this field, that the patient must fit the treatment chosen for him by an expert. This conviction has resulted from extensive research involving a specification of criteria for selection of appropriate candidates, a description of specific technical interventions, and, most importantly, a systematic follow-up study of outcome. As a consequence of their investigations several distinct and successful kinds of brief psychotherapy have been developed. In contrast to this trend, the somewhat global approach to this subject advocated by the authors detracts from the potential value of their book to a large number of readers who look on brief psychotherapy with increasing interest and fascination.

Boston, Mass.

Therapist Disclosure: The Use of Self in Psychotherapy, *by Myron F. Weiner, M.D. Boston, Mass., Butterworths, 1978, 172 pp., $11.95.*

This book is courageous, honest, and full of homely advice. It concerns an important area of psychotherapeutic technique about which too little has been written. The author strikes bravely against the hegemony of the emotionally remote, silent therapist.

One wants to like this book, but it is consistently disappointing. To begin with, the clinical examples are cursory, and in nearly half of them the reader is hard-put even to locate what it is the therapist has disclosed. The balance of examples contain mainly simple statements of positive and negative regard. An early anecdote illustrates several of my difficulties:

> I had worked intermittently with Mr. D., a 25-year-old man, for five years. During one session, in response to his request, I sat with him on my couch, held his hand, and allowed him to literally cry on my shoulder. Previously, he had worked through some homosexual fantasies about me and was beginning to separate me, in his mind, from his deceased mother, whom he had seen as cold, ungiving, and controlling. Several weeks later, when the distortion arose again, I cited this time of physical intimacy to correct his distorted perception of me. (p. 23)

The reader is left to ponder not only what the therapist has disclosed, but also whether the author is aware of the limitations he has imposed on the uses of the transference in this treatment effort of five years' duration. There are indications for such choices, but his failure to discuss them is not reassuring. Initially one is less disturbed by the author's assumption that the technical and theoretical significance of self-disclosing interventions is self-evident than by the level of discussion when it comes. It is disappointing to be brought in the final pages of the book no farther than the reminder that if the therapist elects to have physical contact with his patient (nonsexual touching, we are assured), he or she must keep in mind that such behavior might have magical and even sexual meanings to the patient. Thus, the larger failure of this book is that it does not deal substantively with the technical and theoretical issues of its topic.

In the jungle of jargon that characterizes so much of contemporary writing on psychotherapy the topic of transference management is a beacon in the night. Most varieties of therapy are usefully clarified in terms of how the therapeutic relationship is handled. We are grateful, for example, to Gill and Muslin (1) for their critique of the silent analyst and their thoughtful injunction to greater therapist activity within the framework of psychoanalytic theory and technique. However, outside of psychoanalytic circles the fall of the bastion of the silent therapist has too often become an invitation to chatsy informality. If we elect as therapists to become more active and more open, what are the rules of the game? More specifically, how is therapy shaped and to what extent con-

stricted by interventions that limit transference regression? Spontaneity of the therapist surely has a place in psychotherapy, but when it becomes uncoupled from the careful exercise of professional discipline, and in the absence of an organizing theory of psychotherapy, the results can be disquieting.

The therapist's use of self in conducting psychotherapy is a critically important issue in the advance of the science of our craft. We are, unfortunately, more indebted to Dr. Weiner for the attention his title calls to the topic than for the text of his volume.

Renewal in Psychiatry: A Critical Rational Perspective, *edited by Theo C. Manschreck and Arthur M. Kleinman. Washington, D.C., Hemisphere Publishing Corp. (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1977, 326 pp., $23.50.*

This is a very interesting book, the product of a monthly seminar that examined the role of critical reasoning in psychiatric theory, research, practice, and education. It includes 11 chapters divided into three parts. The first part concerns Issues That Require Clarification and Reconceptualization in the Fields of Psychiatry, the second concerns Issues That Determine the Frontiers and Limits of the Fields of Psychiatry, and the third concerns Issues That Provide Novel and Significant Perspectives in the Fields of Psychiatry.

Part one discusses acute psychosis, social and cultural aspects of psychopathology, and drug dependence. Each chapter is tightly written and well documented and contains an excellent bibliography. With *DSM-III* just around the corner, the authors' discussion of making psychiatry more scientific, measurable, and clear is very timely. I found the drug dependence chapter most interesting. It includes an explanation of Jasinski's structuring of 40 items from the MMPI into three scales: MBG for euphorogenic effects of a drug, the LSD for psychotomimetic effects, and the PCAG for sedative effects. Using this model, psychoactive concomitants of pharmacological agents can be clearly documented and measured, thus moving the subjective sensations into objective data.

Part two contains my favorite chapter, which discusses temporal lobe epilepsy and compares different brain-damaged areas in epilepsy to their associated behavior and diagnostic entities in psychiatry. Since psychiatry seems to be moving more and more toward the organic and away from the functional, this chapter lends credence to the former.

Part three covers patients' expressions about psychiatric hospitalization and the influence of fathers on children; it also includes a chapter titled "Middlehomes: An Introduction to Residence and Developmental Needs," and one titled "A Life History of the Civil Rights Movement." The chapter making a strong case for the importance of fathers for healthy child development is detailed and well documented.

Overall, this book is excellent in places, as mentioned above, but has some chapters that do not really seem to fit. However, I think most psychiatric house officers and practicing psychiatrists will find enough chapters of interest to warrant its perusal. This book has one of the most thorough group of chapter bibliographies I have ever seen.

Omaha, Nebr.

Spatial Organization of Cerebral Processes, *by M. N. Livanov; translated by the Israel Program for Scientific Translations. Jerusalem, Israel, IPST (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1977, 211 pp., $21.50.*

The Cyrillic alphabet and the complexities of grammar combine to make Russian publications inaccessible to most Western readers. This volume was originally published in Moscow in 1973. Essentially, the work concerns spatiotemporal mapping of cerebral potentials in animals and man and summarizes work carried out over a number of years in the author's laboratory. Underlying these efforts are the hope that such maps are analyzable and the postulate that such an analysis will yield explanations of electrogenesis, function and behavior. For many years a large number of investigators have pursued this goal with varying degrees of sophistication and varying, often uncorrelated, degrees of success. High-speed digital computers permit statistical processing of large amounts of data yielding functions such as power-density spectra and auto- and cross-correlations. But such instruments are two-edged swords. Ingenuous experimenters with flawed experimental designs or fallacious postulates can find themselves inundated by a flood of calculations that yield little more than trivial conclusions or epiphenomena.

Readers should approach this volume with some understanding of the scientific climate in the Soviet Union, where neurosciences move within the flume of Pavlovian physiology. In the study of "higher nervous activity" (behavior) conditioned reflexes occupy a central position. As a result, Russian scientists have expended great efforts in attempting to define the electrophysiological and morphological changes as a conditioned reflex emerges.

The volume begins with a consideration of "conditions which determine the spread of excitation in the cerebral cortex," on the assumption that this will clarify "the processes which underlie such major cortical functions as the establishment of a conditioned reflex." This recondite chapter considers the genesis of the activity in rabbit cortex and the significance of widespread synchronization. If the translation is accurate, the research methods are, at least, unusual: "Using a scalped rabbit, we determined the [electric] potentials for the hind limb by direct [sic] stimulation through the bone." Statistical analysis is casual or nonexistent: "Though not particularly large, the difference is based on a sufficient body of material and is therefore significant."

The second chapter attempts to study the synchronization of electrical activity in the cortex during the formation of "time link" and deal with an always stormy problem for Pavlovian physiology, the role of subcortical structures. The final three chapters of the book deal with human activities. The conclusions prove curiously elusive. It may be that the concepts have suffered in translation, but a sample translation may prove illuminating:

> Monitored experiments on man have to date fur-

nished too few data to permit any definitive conclusions. It appears, however, that the principles derived from the role of synchronization in the transmission of excitation in the cerebral cortex of rabbits apply at least in part to the human brain. (p. 109)

These seem to be minor conclusions, particularly since the author's research methods were supposed to rectify the situation in which "the meager achievements in this field have disappointed scientists and even aroused some doubts as to the value of electrophysiology as a tool for the analysis of cortical functions." Anyone familiar with contemporary neurophysiology will recognize the error of even this premise. For example, Mountcastle has shown that the psychophysical identification and discrimination functions for flutter-vibration are identical in man and monkey and that detection functions can be defined in terms of the increment in activity in a particular set of post-central cortical neurons, whereas discrimination functions can be defined in terms of the cyclic entrainment of activity in such cortical neurons. In visual physiology the work of Hubel and Wiesel and that of Blakemore and others has clarified the cortical microcircuitry that underlies feature-extraction and stimulus generalization and has shown the existence of such entities as cortical columns, which constitute the morphological correlates of these neuronal microcircuits.

Are Soviet scientists unaware of or indifferent to contemporary concepts? A review of the bibliography discloses virtually no citation of non-Russian publications for the past 10 years. From these observations one may conclude that constraints on directions of research, lack of access to contemporary Western neuroscience, and linguistic isolation have proved serious impediments in the development of neurosciences in the Soviet Union.

DAVID D. DALY, M.D., PH.D.
Dallas, Tex.

Your Body Biofeedback at Its Best, *by Beata Jencks, Ph.D. Chicago, Ill., Nelson-Hall, 1977, 262 pp., $11.95; $6.95 (paper).*

Bringing together under one cover many terms, techniques, and related concepts is always helpful, but providing too great a variety of choices can be overwhelming. *Your Body Biofeedback at Its Best* alternates precariously between these two poles. The concept of using one's own mind/body processes to aid in the establishment of a more ideal psychophysiological state is a sound one. The intent of this book is to provide a variety of lesson plans to choose from, emphasizing the author's point that one does not need to use electronic biofeedback equipment.

As a long-time user of a variety of biofeedback instruments or tools, I find myself in disagreement with the idea that the mind does not need electronic equipment to get in touch with the body. My experience has been that even with electronic monitoring many minds still cannot make a meaningful contact with the body.

This is an age of expanding development of sophisticated electronic equipment, devices that explore the body in rewarding, painless ways. Electronic biofeedback equipment development is in its infancy. The art and science of the effective application of present-day electronic biofeedback in clinical medicine is only in the beginning stages of its establishment. For many minds (not all), the only route to the establishment of a meaningful sensory awareness of the body will be through this electronic type of biofeedback.

This book is structured around the positive willpower philosophy of "putting your mind to it" in a disciplined way; "success will follow." Without rewarding input via electronic equipment this system has failed in the past. More discipline and a firmer insistent approach is usually only self-defeating. The value of this book lies in its presentation of nonelectronic approaches to the development of sensory awareness with appropriate caution about altered states of consciousness. The book is a scholarly effort. The author is to be congratulated for pulling so much material relating to body awareness together so effectively.

The psychiatrist learns early in his or her training that effectively externalizing and objectifying thoughts and feelings is the beginning of meaningful insight. The techniques developed to provide this constitute the art of psychotherapy. Electronic biofeedback is to body awareness what insight techniques are to psychotherapeutic awareness. After the awareness comes the reliance on one's self for the continued therapeutic effect started in the therapy sessions. It is to these processes that Beata Jencks seems to be referring in her book, which provides ways to continue and build on the successes with electronic biofeedback but not ways to begin the process.

The reader looking for definitions, descriptions, self-reliant techniques, and practices to aid to developing inherent body biofeedback will find this book helpful. It seems to spell out many issues not dealt with in so detailed a manner by authors of books on electronic biofeedback. Yogis, Zen masters, and TM practitioners have lived much of this book's contents. We have learned from them, and we can learn from this book. The author's presentation is an Americanization of the practices of Eastern mystics, perhaps more acceptable and understandable to our Western minds. Read it and get it in perspective in your learning of the role of electronic biofeedback in clinical management of psychosomatic disorders.

This Month's Reviewers

PAUL L. ADAMS, M.D., is Professor of Psychiatry and Vice-Chairperson for Graduate Education, Department of Psychiatry and Behavioral Sciences, University of Louisville School of Medicine, Louisville, Ky.

ROBERT CANCRO, M.D., is Professor and Chairman, Department of Psychiatry, New York University Medical Center, New York, N.Y.

JAMES T. HARTFORD, M.D., is with the Gerontology Research Section, Texas Research Institute of Mental Sciences, Houston, Tex.

DONALD G. LANGSLEY, M.D., is Professor and Chairman, Department of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, Ohio.

RAYMOND HEADLEE, M.D., is Clinical Professor of Psychiatry, Medical College of Wisconsin, Milwaukee, Wis.

PETER P. REILLY, M.D., is in private practice in Providence, R.I.

ANN WOLBERT BURGESS, R.N., D.N.Sc., is Chairperson and Professor, Department of Nursing, Boston College Graduate School of Arts and Sciences, Chestnut Hill, Mass.

C.H. HARDIN BRANCH, M.D., is Program Chief and Interim Director, County of Santa Barbara Mental Health Services, Santa Barbara, Calif.

STANLEY L. OLINICK, M.D., is Clinical Professor of Psychiatry, Georgetown University School of Medicine, Washington, D.C.; he is also a training and supervising analyst and is in private practice in Washington, D.C.

ERIC W. FINE, M.D., is Director, Section on Alcoholism and Other Addictive Disorders, Albert Einstein Medical Center, New York, N.Y., and Associate Professor of Psychiatry and Human Behavior, Jefferson Medical College, Thomas Jefferson University, Philadelphia, Pa.

CARL B. FEINSTEIN, M.D., is Assistant Professor of Psychiatry and Child Health and Development, George Washington University School of Medicine, and Director, Outpatient Department of Psychiatry, Children's Hospital National Medical Center, Washington, D.C.

RUSSELL NOYES, M.D., is Associate Professor of Psychiatry, University of Iowa, Iowa City, Iowa.

DANIEL S.P. SCHUBERT, M.D., PH.D., is Associate Professor of Psychiatry, Case Western Reserve University School of Medicine, and Director of Research, Department of Psychiatry, Cleveland Metropolitan General Hospital, Cleveland, Ohio.

JOHN A. EWING, M.D., is Professor of Psychiatry, University of North Carolina, Chapel Hill, N.C.

LEON J. SAUL, M.D., is Emeritus Professor of Psychiatry, Medical School of the University of Pennsylvania, Philadelphia, Pa.

GEORGE A. CONSTANT, M.D., is in private practice in Victoria, Tex.

WILLIAM A. FROSCH, M.D., is Professor and Vice-Chairman, Department of Psychiatry, Cornell University Medical College, and Medical Director, Payne Whitney Clinic, New York, N.Y.

ROSS F. GRUMET, M.D., is Medical Director, Metropolitan Psychiatric Center, Atlanta, Ga.

MARY ANN BARTUSIS, M.D., is in private practice in Morrisville, Pa.

JEROME M. SCHNECK, M.D., is Attending Psychiatrist, Division of Psychiatric Training and Education, Department of Psychiatry, St. Vincent's Hospital and Medical Center, New York, N.Y.; he is also in private practice in New York.

MICHAEL F. HEIMAN, M.D., is Chief of the Medical/Dental Staff, Stockton State Hospital, Stockton, Calif., and Clinical Instructor in Psychiatry, University of California, Davis, School of Medicine, Davis, Calif.

PHILIPPE E. CHANEL, M.D., is Assistant Professor of Psychiatry, George Washington University School of Medicine, Washington, D.C.

STEVEN S. SHARFSTEIN, M.D., is Director, Division of Mental Health Service Programs, National Institute of Mental Health, Alcohol, Drug Abuse, and Mental Health Administration, Rockville, Md.

P.E. SIFNEOS, M.D., is Professor of Psychiatry, Harvard University, and Associate Director, Department of Psychiatry, Beth Israel Hospital, Boston, Mass.

JUSTIN SIMON, M.D., is in private practice in Berkeley, Calif.

JAMES A. DAVIS, M.D., is Associate Professor of Psychiatry, University of Nebraska Medical Center, Omaha, Neb.

DAVID D. DALY, M.D., PH.D., is Professor of Neurology, Southwestern Medical School, Dallas, Tex.

PHILIP C. ROND, M.D., is Director, University Health Service, Florida State University, Tallahassee, Fla.

Books Received

This listing acknowledges the receipt of recent books. Books of particular interest to the readers of this journal will be reviewed as space permits, and copies of the reviews will be sent to the publishers. Books cannot be returned to the publishers.

Co-operation Between the Sexes: Writings on Women, Love and Marriage, Sexuality and Its Disorders, *by Alfred Adler; edited and translated by Heinz L. Ansbacher and Rowena R. Ansbacher. Garden City, N.Y., Anchor Books (Doubleday & Co.), 1978, 455 pp. $3.95 (paper).*

Psychiatric Diagnosis: Exploration of Biological Predictors, *edited by Hagop S. Akiskal, M.D., and William L. Webb, M.D. New York, N.Y., SP Medical & Scientific Books (Spectrum Publications), 1978, 490 pp., $25.00.*

The Mind in Sleep: Psychology and Psychophysiology, *edited by Arthur M. Arkin, John S. Antrobus, and Steven J. Ellman. New York, N.Y., Lawrence Erlbaum Associates (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1978, 624 pp., $29.95.*

It's Scary Sometimes, *by Marcella Bacigalupi, Georgio Bini, Claudio Costantini, and Piero Fossati; drawings by the children themselves. New York, N.Y., Human Sciences Press, 1978, unnumbered pages, $6.95.*

Psychopharmacology of Thiothixene, *by Thomas A. Ban, M.D. New York, N.Y., Raven Press, 1978, 236 pp., $12.50.*

Psychiatry Observed, *by Geoff Baruch and Andrew Treacher. Boston, Mass., Routledge & Kegan Paul, 1978, 254 pp., $11.50 (paper).*

Motivation: Theories and Principles, *by Robert C. Beck. Englewood Cliffs, N.J., Prentice-Hall, 1978, 459 pp., $12.95.*

Neurochemical and Immunologic Components in Schizophrenia, *edited by Daniel Bergsma, M.D., and Allan L. Goldstein, Ph.D. New York, N.Y., Alan R. Liss, 1978, 425 pp., $46.00.*

A Bibliography in Dynamic, Familial and Social Psychiatry, *by John Birtchnell and Sheila Hafter Gray. Colchester, England, Society of Clinical Psychiatrists, 1978, 135 pp., 50 English pence (paper).*

Mechanisms of Nervous Disorder: An Introduction, *by David Bowsher, M.D., Ph.D. Oxford, England, Blackwell Scientific Publications (Philadelphia, Pa., J.B. Lippincott Co., distributor), 1978, 102 pp., $9.75 (paper).*

Human Growth and Development: Wolfson College Lectures 1978, *edited by Jerome S. Bruner and Alison Garton. New York, N.Y., Clarendon Press (Oxford University Press), 1978, 167 pp., $10.50; $5.50 (paper).*

The Impact of Alcoholism, *by Steven F. Bucky, Ph.D., Richard Boyatzis, Ph.D., Jere Bunn, Barbara Czesnik, M.A., Anthony Del Nuovo, M.A., Gloria Cody, Ph.D., Douglas Harry, LL.B., David Jacobs, Ph.D., Rosalie Jesse, Ph.D., James Massman, M.D., and Adrienne Nesfadd, Ph.D. Center City, Minn., Hazelden, 1978, 120 pp. $3.50 (paper).*

Annual Review of the Schizophrenic Syndrome 1975–1977, *edited by Robert Cancro, M.D. New York, N.Y., Brunner/Mazel, 1978, 636 pp., $27.50.*

Principles and Practice of Child Psychiatry, *by Stella Chess, M.D., and Mahin Hassibi, M.D. New York, N.Y., Plenum Press, 1978, 486 pp., $20.00.*

Basic Principles and Techniques in Short-Term Dynamic Psychotherapy, *edited by Habib Davanloo, M.D. New York, N.Y., SP Medical & Scientific Books (Spectrum Publications), 1978, 549 pp., $30.00.*

Neurological Pathophysiology, 2nd ed., *by Sven G. Eriasson, M.D., Ph.D., Arthur L. Prensky, M.D., and William B. Hardin, Jr., M.D. New York, N.Y., Oxford University Press, 1978, 442 pp., $16.95; $9.95 (paper).*

Client Participation in Human Services: The Prometheus Principle, *edited by Constance T. Fischer and Stanley L. Brodsky. New Brunswick, N.J., Transaction Books, 1978, 241 pp., $12.95.*

The Scientific Evaluation of Freud's Theories and Therapy: A Book of Readings, *edited by Seymour Fisher and Roger P. Greenberg. New York, N.Y., Basic Books, 1978, 447 pp., $25.00.*

Primary Prevention of Psychopathology, Vol. II: Environmental Influences, *edited by Donald G. Forgays. Hanover, N.H. University Press of New England, 1978, 249 pp. $15.00.*

Effective Ingredients of Successful Psychotherapy, *by Jerome D. Frank, Rudolf Hoehn-Saric, Stanley D. Imber, Bernard L. Liberman, and Anthony R. Stone. New York, N.Y., Brunner/Mazel, 1978, 212 pp., no price listed.*

Directory of Unpublished Experimental Mental Measures Vol. 2, *by Bert Arthur Goldman, Ed.D., and John Christian Busch, Ed.D. New York, N.Y., Human Sciences Press 1978, 472 pp., no price listed.*

Neuroses: A Comprehensive and Critical View, *by Melvin Gray, M.D. New York, N.Y., Van Nostrand Reinhold Co., 1978, 314 pp., $15.95.*

Edward Jarvis and the Medical World of Nineteenth-Century America, *by Gerald N. Grob. Knoxville, Tenn., University of Tennessee Press, 1978, 287 pp., $14.00.*

Alcohol, Other Drugs and Violent Death, *by Paul W. Haberman and Michael M. Baden, M.D. New York, N.Y., Oxford University Press, 1978, 130 pp., $13.95.*

I've Done So Well—Why Do I Feel So Bad? *by Celia Halas, Ph.D., and Roberta Matteson, Ph.D. New York, N.Y., Macmillan Publishing Co., 1978, 304 pp., $10.95.*

Within Reach: Providing Family Planning Services to Physically Disabled Women, 2nd ed., *by Julia Hale-Harbaugh, Ann Duecy Norman, Jane Bogle, and Susan Shaul; illustrated by Katie Venables. New York, N.Y., Human Sciences Press, 1978, 48 pp., $2.95 (paper).*

Developments in Opiate Research, *edited by Albert Herz. New York, N.Y., Marcel Dekker, 1978, 414 pp., $35.00.*

Projective Assessment: Methods in Clinical Psychology, Vol. 1, *by Robert R. Holt. New York, N.Y., Plenum Press, 1978, 330 pp., $17.50.*

Prediction and Research: Methods in Clinical Psychology, Vol. 2, *by Robert R. Holt. New York, N.Y., Plenum Press, 1978, 324 pp., $17.50.*

Psychiatric Drugs: A Desk Reference, 2nd ed., *by Gilbert Honigfeld and Alfreda Howard. New York, N.Y., Academic Press (Harcourt Brace Jovanovich), 1978, 236 pp., no price listed (paper).*

Being and Loving, *by Althea Horner. New York, N.Y., Schocken Books, 1978, 142 pp., $9.95.*

Drugs of Abuse: Handbook of Psychopharmacology, Vol. 12, *edited by Leslie L. Iversen, Susan D. Iversen, and Solomon H. Snyder. New York, N.Y., Plenum Press, 1978, 412 pp., $32.50.*

Biology of Mood and Antianxiety Drugs: Handbook of Psychopharmacology, Vol. 13, *edited by Leslie L. Iversen, Susan D. Iversen, and Solomon H. Snyder. New York, N.Y., Plenum Press, 1978, 430 pp., $32.50.*

Inheritance of Creative Intelligence, *by Jon L. Karlsson, Ph.D., M.D. Chicago, Ill., Nelson-Hall, 1978, 200 pp., $14.95; $7.95 (paper).*

Handbook of Sex Therapy, *edited by Joseph LoPiccolo and Leslie LoPiccolo. New York, N.Y., Plenum Press, 1978, 526 pp., $29.50.*

Dimensions of Human Potentiality: The Collected Works of Eugene Pumpian-Mindlin, *edited by Michael T. McGuire, M.D. New York, N.Y., SP Medical & Scientific Books (Spectrum Publications), 1978, 333 pp., $15.00.*

Quality of Life in Severely and Profoundly Mentally Retarded People: Research Foundations for Improvement, *edited by C. Edward Meyers. Washington, D.C., American Association on Mental Deficiency, 1978, 384 pp., $14.95.*

Cerebral Logic: Solving the Problem of Mind and Brain, *by Charles W. Needham, M.D., M.Sc. Springfield, Ill., Charles C Thomas, 1978, 205 pp., $12.75.*

Paradox and Counterparadox: A New Model in the Therapy of the Family in Schizophrenic Transaction, *by Mara Selvini Palazzoli, M.D., Luigi Boscolo, M.D., Gianfranco Cecchin, M.D., and Giuliana Prata, M.D.; translated by Elisabeth V. Burt. New York, N.Y., Jason Aronson, 1978, 186 pp., no price listed.*

Self-Starvation: From Individual to Family Therapy in the Treatment of Anorexia Nervosa, *by Mara Selvini Palazzoli; translated by Arnold Pomerans. New York, N.Y., Jason Aronson, 1978, 289 pp., no price listed.*

Les Voies Nouvelles de la Dépression, *edited by P. Pichot. Paris, France, Masson, 1978, 200 pp., no price listed (paper).*

BT: Behavior Therapy. Strategies for Solving Problems of Living, *by Spencer A. Rathus, Ph.D., and Jeffrey S. Nevid, Ph.D. New York, N.Y., Signet (New American Library), 1978, 312 pp., $2.25 (paper).*

Propranolol and Schizophrenia, *edited by Eugene Roberts, Ph.D., and Peter Amacher, Ph.D. New York, N.Y., Alan R. Liss, 1978, 150 pp., $15.00.*

Estudios Sobre el Suicidio, *by Enrique Rojas. Barcelona, Spain, Salvat Editores, 1978, 539 pp., no price listed (paper).*

Violence and Responsibility: The Individual, the Family and Society, *by Robert L. Sadoff, M.D. New York, N.Y., SP Medical & Scientific Books (Spectrum Publications) (Halsted Press, John Wiley & Sons, distributor), 1978, 133 pp., $14.95.*

Toward Intimacy: Family Planning and Sexuality Concerns of Physically Disabled Women, 2nd ed., *by Susan Shaul, Jane Bogle, Julia Hale-Harbaugh, and Ann Duecy Norman; illustrated by Katie Venables. New York, N.Y., Human Sciences Press, 1978, 61 pp., $2.50 (paper).*

The Trauma of Time: A Psychoanalytic Investigation, *by Irvine Schiffer. New York, N.Y., International Universities Press, 1978, 271 pp., $15.00.*

Consciousness and Self-Regulation: Advances in Research and Theory, Vol. 2, *edited by Gary E. Schwartz and David Shapiro. New York, N.Y., Plenum Press, 1978, 428 pp., $22.50.*

Methods of Group Psychotherapy and Encounter: A Tradition of Innovation, *by Jerrold Lee Shapiro. Itasca, Ill., F.E. Peacock, 1978, 354 pp., $12.50.*

Schizophrenia: Science and Practice, *edited by John C. Shershow. Cambridge, Mass., Harvard University Press, 1978, 239 pp., $15.00.*

Mind and Madness in Ancient Greece: The Classical Roots of Modern Psychiatry, *by Bennett Simon, M.D. Ithaca, N.Y., Cornell University Press, 1978, 325 pp., $17.50.*

Am J Psychiatry 135:10, October 1978

OFFICIAL ACTIONS

Report of the Secretary: Summary of Meetings of Board of Trustees and Executive Committee May 1977–May 1978

IT IS MY personal and constitutional privilege to report the actions of the Board of Trustees and its Executive Committee over the past year. These items do not include many matters that have been referred to appropriate components for further study and recommendation. The recommendations and related actions of the Assembly are included with the relevant items.

This report is arranged in alphabetical order according to topic except for the first item concerning the adoption of the consent calendar concept, which permits the Board and Executive Committee to vote en bloc on matters seen to be less controversial and often of an administrative nature.

The actions reflect the varied issues that have been considered by the Board over the year. There have been internal issues, such as continuing education, constitutional change, elections and related matters, fiscal and budget issues, problems of the chronic patient, as well as a need to remodel or relocate our Central Office facilities to meet the needs of our growing membership activities and staff support. The Board has also been involved in responding to external forces, such as legislation (proposed or enacted), establishment of the President's Commission on Mental Health, activities of related organizations, and so forth.

I would remind you that every member of APA is privileged to attend any session of components of the Association except for meetings of the Ethics Committee or when a component is in Executive Session. Recommendations for consideration by the Board or other components are most welcome. The Board (or its Executive Committee acting as its agent) took the following actions.

PROCEDURE

1. To provide more time for policy discussion at meetings, the Executive Committee (Sept. '77) and the Board (Dec. '77) voted to employ the consent calendar concept for use at all of their meetings.

ANNUAL MEETING

1. Authorized the Program Committee to review all scientific programs held at the annual meeting, including those beginning on Saturday and Sunday preceding the meeting that are not sponsored by another scientific organization, before they are included in the program schedule (Bd., Dec. '77).
2. Approved waiving annual meeting registration fees for foreign visitors, beginning in 1979, and changing the Policy and Procedural Manual for the annual meeting to reflect this (Bd., Dec. '77).
3. Endorsed the action of the Reference Committee to authorize staff to proceed with a direct advance registration mailing to the membership promoting the annual meeting and highlighting continuing medical education requirements (Bd., Dec. '77).
4. Revised the Policy and Procedural Manual for the annual meeting.
5. Accepted the recommendation of the Committee on Women that, where relevant, officials in cities being considered for APA annual meetings in the 1980s be reminded of the Association's resolution on the Equal Rights Amendment (Ex.C., June '77). Voted to approve recommendation of the Assembly as follows: APA will notify legislatures of states that have not ratified ERA of our theoretical policy favoring the ERA and that we shall attempt active implementation by changing convention plans as soon as possible (Bd., Dec. '77).

AWARDS

1. Voted to reduce the Isaac Ray Honorarium to $1.500 and authorized it to be awarded every other year (Bd., Dec. '77).
2. Voted to establish the honorarium for the Foundations Fund Prize for Research in Psychiatry at $1,500 (Bd., Dec. '77).
3. Voted to establish the Blanche F. Ittleson Award at $2,500 (Bd., Dec. '77).

CENTRAL OFFICE

1. Established an Ad Hoc Committee on the Central Office as recommended by the Council on Internal Organization and its House Committee that would include one member representing the Assembly. Its mandate is to study the options available for meeting the need for a Central Office building, report to the Board in December 1977, and begin to

This is an edited version of the report presented by the Secretary to the annual business meeting in Atlanta, Ga., May 9, 1978.

educate the membership immediately through usual channels (including *Psychiatric News*) and alert the Assembly to the problem so it may become actively involved in future planning (Ex.C., Sept. '77).

2. Ratified an emergency action of the chairperson of the House Committee and the Medical Director to install a new furnace at an estimated cost of $14,524, to be charged to the Reserve for Future Expansion and Development Account (Ex.C., Sept. '77).

3. Terminated the Ad Hoc Committee on the Central Office with thanks and authorized the House Committee to be the implementing body to review alternatives for obtaining new facilities for the Association, including remodeling the present facilities, leasing, constructing a building, or purchasing a building; authorized staff to a) sign a sales contract for real property located at Connecticut Avenue and Hillyer Place or other suitable site in the amount of $800,000 and to include in its major stipulations that APA be allowed at least 90 days from the date of the contract to make a final decision; b) obtain architectural and engineering studies and test borings, at an estimated cost of $17,500, to satisfy itself that a building permit can be obtained so as to determine the feasibility of purchasing the property for construction of an office building; and c) deposit $50,000 in an escrow account as earnest money—such earnest money to be returned to APA if the sale is not concluded. Authorized the President, Speaker, and Medical Director to use the emergency mechanism if a superior option was available to allow flexibility for rapid action if necessary; authorized a mail or telephone poll of the Board if there is a need to move quickly, and considered the possibility of holding a meeting of the full Board at the time of the presently scheduled meeting of the Executive Committee in February 1978; voted to request the Editor of *Psychiatric News* to advise the membership of the discussion of the Board around these issues; voted to request staff to send members of the Board full reports of the House Committee and other relevant material to assist them in their deliberations (Bd., Dec. '77).

4. Authorized staff to submit a sales contract for the purchase of the Connecticut and Hillyer property with the same provisions as the previous contract except a) the period allowed for the determination of the feasibility of purchasing the lot be reduced from 120 to 90 days and b) the addition of a clause to ensure that APA's rights are vested prior to closing; authorized discretionary use of earnest money (up to $10,000) to be nonrefundable if APA decides not to purchase the lot even if the feasibility study yields positive results (Ex.C., Feb. '78).

5. Ratified the emergency action of the President, Speaker, and Medical Director to authorize staff to submit a revised sales contract on the property at Connecticut Avenue and Hillyer Place, Washington, D.C., in the amount of $869,220, with $10,000 of the earnest money to be nonrefundable if the sale is not consummated (Bd., Mar./Apr. '77).

6. Approved selection of the architectural firm of Hartman Cox and authorized staff to enter into contractual arrangements with them (Bd., Mar./Apr. '77).

CONSTITUTION AND BY-LAWS

1. Chapter One, Section 8, of the By-Laws ("Members") and Chapter Eight, Section 6, of the By-Laws ("Privileges and Responsibilities") involve the question of Life Status and the "95" formula for dues exemption. Voted against separating the definition of Life Status from the "95" formula in the amendments for the ballot in 1979—the amendment to Chapter One, Section 8, will provide for Life Member and Life Fellow (and the new Life Associate Member) to be defined by the following formula: years of membership as an Associate Member, General Member and/or Fellow, plus the member's age to equal 95, and will also require dues-exempt members to pay a reduced subscription rate for the *American Journal of Psychiatry* and *Psychiatric News* (Bd., Mar./Apr. '77).

2. Chapter One, Section 12, of the By-Laws ("Members"). Approved the following amendment to go on the ballot in 1979: "Inactive members of any category shall be those whom the Board has, for sufficient reason, excused from paying dues" (Bd., Dec. '77).

3. Chapter Eight, Section 5, of the By-Laws ("Privileges and Responsibilities") and Chapter Nine, Section 1, of the By-Laws ("Voting"). Approved amendments for the ballot in 1979 that would require petitions for candidates and referenda to be in the office of the Secretary by December 1 rather than December 15 of the year preceding the next election (Bd., Mar. '78).

4. Chapter One ("Members"). Authorized amendments to allow for exemptions to CME requirements as "exempted by the Board" to maintain membership in good standing, and a requirement for 8 rather than 5 years as General Member to be eligible for Fellowship status for the 1979 ballot. Also authorized a change in the *Operations Manual* to require 10 years of experience in psychiatry to be eligible for Fellowship status (Ex.C., Sept. '77).

5. Approved the recommendations for constitutional change prepared by the Joint Conference Committee on the Key Conference Recommendations; the Committee on Constitution and By-Laws reviewed them to ensure that they were in order; the amendments were submitted to the Secretary 60 days before the annual meeting and were presented to the membership at the annual meeting in 1978, so they can be voted on in the 1979 ballot (Bd., Dec. '77).

COUNCILS, COMMITTEES, TASK FORCES, AND COMMISSIONS

1. Renewed for one more year the following ad hoc committees: on Interprofessional Services; on Election Procedures; to Plan a Conference on the Chronic Mental Patient; on Implementation of the 1976 Referenda on Psychiatric Certification; and to Review *Psychiatric News*. The Ad Hoc Committee on Biographical Data and the Ad Hoc Committee to Plan a Working Conference on Law and Psychiatry were not renewed (Bd., May '77).

2. On recommendation of the Council on International Affairs, approved the "Resolution on Behalf of Argentine Scientists" decrying the general pattern of violations of human rights by the military government of Argentina, and asked that the resolution be communicated to the Organization of American States' Inter-American Commission on Human Rights, the State Department of the United States and concerned congressional committees, and the President of Argentina (Bd., May '77).

3. Established three subcommittees of the Program Committee (Film, Video, and Spouses Scientific Program) (Bd., Dec. '77).

4. Approved the Position Statement on Active Treatment, pending approval by the Assembly (Bd., Dec. '77).

5. Established a Committee on Asian-American Psychia-

trists on recommendation of the previous task force (Ex.C., June '77).

6. Terminated the Committee on Psychiatric Nursing, with thanks (Bd., Dec. '77).

7. Endorsed the concept of providing consultative services to the Commission on Professional and Hospital Activities and recommended to the Reference Committee that travel expenses for a task force within the Council on Mental Health Services be authorized from the 1978 Reference Committee Contingency Fund (Bd., Dec. '77).

8. Established a Committee to Review *Psychiatric News* within the Council on Internal Organization with a mandate to make a formal report every two years to the Council, Reference Committee, and the Board and inclusion of the charge in the *Operations Manual* (Bd., Dec. '77).

9. Established a Committee on Psychiatry and Foreign Affairs within the Council on International Affairs (Bd., Dec. '77).

10. Authorized the Ad Hoc Committee on the President's Commission on Mental Health to prepare a position paper for the PCMH based on 10 points identified by the Ad Hoc Committee and the Assembly to meet the January 3, 1978, deadline for input to the PCMH (Bd., Dec. '77) and ratified the emergency action taken by the President, Speaker, and Medical Director to approve the APA position on the Interim Report of the PCMH (Ex.C., Feb. '78).

11. Endorsed the AMA standards for the education and training of advanced emergency medical technicians and approved in principle becoming a sponsoring organization for the accreditation program and to use the emergency mechanism to so sponsor if necessary (Bd., Dec. '77).

12. Endorsed efforts by the Council on Medical Education and Career Development with necessary agencies to bring about full voting representation of psychiatry on any certification board for emergency medicine (Bd., Dec. '77).

13. Asked a newly forming Task Force on Emergency Psychiatric Care to develop a grant proposal to develop standards for emergency services (Bd., Dec. '77).

14. Authorized the Commission on Judicial Action to prepare an amicus curiae brief in the case of *Ferraro & Kaviani v. the USA*, which has to do with whether a patient who had multiple hospitalizations in VA hospitals should have been retained until his treatment was finished (Bd., May '77).

15. Authorized the Commission on Judicial Action to file an amicus curiae brief on the side of the plaintiffs in *Parham v. J.L. and J.R.*, which involved long-term commitment of two minimally disabled children in the State of Georgia, provided that the Georgia District Branch approves (Ex.C., June '77).

16. Authorized the Commission on Judicial Action to find a witness to testify in the case of *Rone V. Fireman* on behalf of the Department of Mental Health at the request of the Ohio Psychiatric Society (Ex.C., Sept. '77); and approved the recommendation that Dr. Douglas Lenkoski testify on behalf of APA on the side of the Ohio Department of Mental Health in this case (Bd., Dec. '77).

17. Authorized $3,000 to assist in preparing an amicus curiae brief in the *Bellah v. Greenson* case from the special $25,000 fund for the Commission on Judicial Action to assist district branches at the local level (Bd., Dec. '77).

18. Authorized the Commission on Judicial Action to provide an amicus curiae brief for an appeal in Texas in the Fifth Circuit Court on issues of informed consent and prediction of dangerousness (Bd., Mar. '78).

19. Encouraged the Committee on Comprehensive Health Planning to collaborate with the Joint Commission on Government Relations to visit the area councils and facilitate collaboration between the district branches and Health System Agencies (Bd., Dec. '77).

20. Approved four recommendations of the Committee on Continuing Education regarding a) cooperation with the Association of American Medical Colleges to develop review procedures for audiovisual materials, b) the committee's responsibility for the technical and education review process, c) Category I credit for formal university programs that enhance practice, and d) disallowing personal psychoanalysis for CME credit (Ex.C., June '77).

21. Approved initial input to the regulatory process of PL 94-484, Health Professionals Educational Assistance Act (Ex.C., June '77); approved the response to the proposed regulations for the training of physician assistants in accordance with PL 94-484 (Bd., Dec. '77).

22. Endorsed a document, "Toward a National Policy for Psychiatric Manpower—Problems, Assets and Recommendations," which had been prepared conjointly by the Executive Committees of the American Association of Chairmen of Departments of Psychiatry and the American Association of Directors of Psychiatric Residency Training (Bd., Dec. '77).

23. Approved the recommendation of the Committee on Standards of Practice and Third-Party Payment that APA not make a national study of the Insurance Claim Project (field tested in California) and that ongoing work on confidentiality issues continue within the Committee on Confidentiality and the Committee on Peer Review (Bd., Dec. '77).

24. Endorsed an Area II Action Paper approved by the Assembly calling for retention of the Commission on Certification in Administrative Psychiatry until appropriate alternatives are found within or outside APA and rescinded previous action of the Board to phase out the Commission in 1989 (Bd., Dec. '77).

25. On recommendation of the Assembly, approved publicizing the fourth edition of the *Physicians' Current Procedural Terminology* to the membership and encouraged its use in insurance reporting (Bd., Dec. '77).

26. Approved continuing support to the Fellowship program and exploring other sources to fund the program subsequent to the termination of support by the National Medical Fund (Ex.C., June '77).

27. Approved a reduction in size of the fellowship program to 20 Fellows after 1979 (10 second-year Fellows and 10 to be chosen that year); requested the Budget Committee to plan for continuing support and authorized seeking outside funding to partially or, if possible, totally underwrite the expenses to continue the program, including support by the Fellows' residency training program, donations from Fellow alumni, and donations from APA members (Bd., Mar. '78).

28. Endorsed the NIMH Minority Fellowship Program and urged NIMH to continue its support (Ex.C., June '77).

29. Approved inviting an observer-consultant representative of the APA/NIMH Minority Fellows to the meetings—this individual to be elected by the current Fellows and alumni in the program (Bd., Mar. '78).

30. Approved the recommendations of the Committee on Liaison with the American Hospital Association and the Commission on Standards of Practice and Third-Party Payment that APA support the voluntary cost containment program in principle and encourage individuals to support the program in local institutions; that APA take an official pos-

tion that any voluntary cost containment effort must recognize continuing and existing psychiatric services, including research and education, and must give special attention to psychiatric services provided to children, and that the Assembly request district branches and members to inform APA staff of the adverse effects of cost containment as regards psychiatric services in their areas; authorized the Medical Director, in cooperation with appropriate APA components, to seek outside funding to support a study of cost containment (Bd., Mar. '78).

31. Approved the recommendation of the Assembly that APA cease referring to its members as "mental health professionals" and cease using the term "mental health benefits," wherever possible (Bd., Dec. '77).

32. Informally authorized the Joint Commission on Government Relations to coordinate APA's response to the "Legislative Guide" developed by NIMH and currently being published in sections in the *Mental Health Disabilities Law Reporter* of the American Bar Association. The first section concerning civil commitment was distributed to APA members for comment in December 1977. Responses were received, reviewed, and summarized in a special edition of the *Legislative Newsletter* (March 1978) and submitted to the editorial board of the ABA publication for publication in the MHDLR (Bd., Mar./Apr. '78).

33. In collaboration with the President's Commission on Mental Health, APA (Ad Hoc Committee to Plan a Conference on the Chronic Mental Patient) held a conference on this topic in January 1978. Dr. Talbott, chairperson of the ad hoc committee, presented a set of recommendations that are embodied in the preliminary report of the conference to a task panel of the PCMH (Ex.C., Feb. '78). The ad hoc committee is preparing a conference report and working papers of the conference for publication. The Board endorsed the recommendation of the Joint Commission on Public Affairs calling for APA to give high priority to the problems of this patient group and to discuss the composition and future work of a component concerning these issues (Ex.C., Feb. '78).

ELECTIONS AND TERMS

1. Voted to continue the present plurality system of balloting for one more year and then to conduct preferential balloting for three years when there are more than two candidates for one position (Ex.C., June '77).

2. Approved the date of receipt at the Central Office as the deadline for APA ballots, since postmarks are often illegible or nonexistent (Ex.C., May '77).

3. Authorized staff to print on the ballot, "no information submitted," if a candidate's biographical data are not submitted on the official form (Ex.C., June '77).

4. Approved the recommendation of the Ad Hoc Committee on Election Procedures that the President (rather than the Secretary) approve the APA ballot (Ex.C., June '77).

5. Approved printing biographical data in straight alphabetical order on the reverse of the APA ballot, without regard to the order of rotation of names on the front of the ballot (Ex.C., June '77).

6. Endorsed the recommendation of the Ad Hoc Committee on Election Procedures regarding clarification of presentation of biographical data for candidates for election to APA offices, particularly with regard to errors and number of items permitted, and authorized incorporation in the *Operations Manual* (Ex.C., Feb. '78).

7. Authorized the Committee of Tellers and staff to carry out a run-off election, if necessary (Ex.C., Feb. '78).

ETHICAL MATTERS

1. Approved a basic change in procedure that all ethical complaints (no matter where they arise) must be referred to the APA Secretary before there can be any hearing, evaluation of complaint, or other action—and approved the "Procedure for handling allegations of unethical conduct," as submitted by the Ethics Committee (Ex.C., June '77).

2. Reaffirmed its previous opinion that the Nuremberg Code and the Declaration of Helsinki are still guides to be used by physicians doing research on human subjects. (The Ethics Committee was asked to develop guidelines for the acceptance of research funding by psychiatrists and to establish a task force to assist.) (Bd., Dec. '77).

3. Approved the Ethics Committee recommendation that any charges of unethical conduct against Corresponding Fellows or Members or Distinguished or Honorary Fellows be referred to the appropriate component of the World Psychiatric Association (WPA) for advice and recommendations to assist the APA Ethics Committee in reviewing the complaint (Bd., Dec. '77).

4. Established a Committee on Abuse and Misuse of Psychiatry in the United States within the Council on Emerging Issues to have liaison with its counterpart WPA committee, and authorized the charge for the *Operations Manual* to include receiving complaints about ongoing abuses of psychiatry in the United States, referring those that are appropriate to the APA Ethics Committee and referring general issues that do not concern a particular practitioner to the WPA committee for discussion and recommendation (Bd., Dec. '77).

5. Approved sending a letter from the APA President to the Judicial Council of the AMA with comments and suggestions about proposed changes in the new *AMA Principles of Medical Ethics*. (The APA Constitution requires APA members to abide by the AMA principles.) (Bd., Mar. '78).

6. Approved the Assembly position statement on "Abuse of Psychiatry: Continuing Use of Psychiatry and Psychiatrists for Political Purposes," and agreed to empower APA's delegate to the World Psychiatric Association General Assembly (Dr. Weinberg, President) to decide what specific motions he will support and/or introduce at the meeting of the General Assembly; and approved the Assembly's recommendation that APA urge the World Psychiatric Association to establish a mechanism to study reports of political abuse of psychiatry and empowered APA's delegate to bring this to the attention of the General Assembly if he deems it appropriate to do so (Ex.C., June '77).

FISCAL MATTERS

1. Authorized attendance of an AMA delegate to report to the May and fall meetings of the Assembly, and $500 for travel expenses to the fall meeting (Bd., May '77).

2. Voted, on recommendation of the Assembly and the Committee on Constitution and By-Laws, to include the immediate past Speaker of the Assembly and the Treasurer as voting members of the Budget Committee and to revise the *Operations Manual* to include this charge (Bd., Dec. '77).

3. Approved termination of Suter Associates Retirement

Planning Company as administrator of the APA tax-deferred annuity plan (Prudential) (Ex.C., June '77).

4. Approved funding from the Board Contingency Fund to cover planning and development expenses for the 1977 fiscal year ($2,000 for the French meeting and $2,950 for the Pacific Congress of Psychiatry) and recommended that the budgets for fiscal years 1978 and 1979 include funding to support these costs for the Second Pacific Congress with the expectation that APA would be reimbursed from income from these meetings (Ex.C., June '77).

5. Approved APA's participation in a nationwide survey of psychiatrists, conducted by the Medical Activities and Manpower Projects Division of Research in Medical Education at the University of Southern California School of Medicine (Ex.C., June '77).

6. Approved in principle the preliminary proposal for APA's fourth Psychiatric Knowledge and Skills Self-Assessment Program and authorized the PKSAP-IV Steering Committee and staff to enter into further negotiations with the National Board of Medical Examiners (Ex.C., June '77).

7. Approved the program specifications and cost estimate in the amount of $147,305, as proposed by the National Board of Medical Examiners to assist APA in the development of PKSAP-IV (Bd., Dec. '77).

8. Authorized a voluntary fund-raising campaign to the APA membership as the first phase in financing a survey on public attitudes toward psychiatry, and authorized expenditure of $5,000 for the purpose, with the understanding that the money thus expended will be returned to APA from receipts of the drive (Ex.C., June '77).

9. Ratified the emergency action of the President, Speaker, and Acting Medical Director to seek outside funding by submitting a contract proposal to NIMH on "Psychopharmacologic Criteria Development" by the deadline of August 7, 1977; this contract will provide about $10,000 to cover preparation of a document containing such criteria (Ex.C., June '77).

10. Approved funding for the Commission on Psychiatric Therapies in the amount of $10,000 for the first year from the Board Contingency Fund to establish the Commission in May 1978 and authorized the Commission to seek outside funding to supplement APA's support (Bd., Dec. '77).

11. Approved a 7% cost-of-living increase for APA staff as of October 2, 1977 (Bd., Dec. '77).

12. Approved revising the travel regulations to allow reimbursement for the actual cost of rail travel (regardless of class) up to the first-class air travel cost, and increased reimbursement for automobile travel to 15 cents per mile (Bd., Dec. '77).

13. Ratified the mail ballot of the Board for the purchase of a minicomputer in the amount of $103,310 (Bd., Dec. '77).

14. Approved providing complimentary subscriptions to all member associations of the World Psychiatric Association via first class mail (Bd., Dec. '77).

15. Voted, on recommendation of the Assembly, to reimburse deputy district branch representatives for transportation expenses (excluding food and lodging) to the spring and fall meetings of the area councils to bring this level of funding to that of the district branch representative, and to fund these expenses from the Board Contingency Fund in 1978 and to instruct the Budget Committee to include this item in the 1979 budget (Ex.C., Feb. '78).

16. Approved the recommendations of the Treasurer for distribution of surplus funds from 1977 operations and excess receipts from the VI World Congress of Psychiatry (Ex.C., Feb. '78).

17. Authorized Dr. Reginald Lourie, in collaboration with the Medical Director, to seek outside funding in the name of APA to support the program of the Inter-American Council of Psychiatric Associations to use the communications satellite to exchange scientific information between components of the IACPF (Ex.C., Feb. '78).

18. Approved APA's being represented in the AMA House of Delegates by one delegate and one alternate delegate and authorized funding ($1,180) from the Board Contingency Fund to support their attendance at the annual and interim meetings of the AMA House of Delegates in 1978 and instructed the Budget Committee to include this in the 1979 budget (Ex.C., Feb. '78).

19. Voted to inform the AMA that APA wishes to have a Section Council on Psychiatry within the AMA as soon as APA has been notified that the Association is approved for a delegate and alternate delegate in the AMA House of Delegates and directed the Budget Committee to include at least $5,000 in the 1979 budget to fund the Section Council (Ex.C., Feb. '78).

20. On recommendation of the Assembly, voted to retain a Consultant in Parliamentary Procedure to assist in the conduct of meetings of the Assembly in 1978; to fund these expenses from the Trustees' Contingency Fund in 1978 (Ex.C., Feb. '78).

21. Authorized $1,000 in support of the National Association of Insurance Commissioners' Malpractice Closed Claims Study (Bd., Mar. '78).

INSURANCE

1. Approved rate increases (in the APA members' insurance plan) for hospital and nursing care by 50%, major medical insurance by 35%, and a moderate increase for disability insurance for those over 50, because of inflation (Bd., Dec. '77).

2. Approved new rates for professional liability insurance with the proviso that the Committee on Professional Liability Insurance continue to obtain additional data during the next year on which new rate structures can be based (Bd., Dec. '77).

3. Approved reducing all benefits in APA's Major Medical Plan as a temporary measure in keeping with APA's policy of equal coverage for mental and physical illnesses; charged the Committee on Member, Life, Accident and Health Insurance to seek ways to affiliate APA's plan with a larger group, and to explore alternatives if the present insurance plan cannot remain fiscally sound (Bd., Dec. '77). Voted to reconsider its action, but a motion to limit reductions in only psychiatric benefits did not pass and the action of December 1977 stands (Bd., Mar./Apr. '77).

LIAISON WITH OTHER ORGANIZATIONS

1. Authorized APA's becoming an affiliate member of the American Association for Comprehensive Health Planning for one year ($200) (Bd., May '77).

2. Favored ratification of the By-Laws of the Council of Medical Specialty Societies which would allow societies having conjoint examining boards membership within the CMSS (Bd., May '77).

3. Granted the request of the American College of Mental Health Administrators to use the American Psychiatric As-

sociation as a mail address and for purchase of services (Ex.C., June '77).

4. Approved the American Board of Psychiatry and Neurology (ABPN) policy concerning qualifications of applicants with non-U.S. training, and the criterion for approval of the first post-graduate year of training at a training center located outside the United States and Canada, as submitted by the ABPN (Ex.C., June '77).

5. Voted to suggest to the ABPN that the issue of the present system of tenure and a possible six-year term for directors be studied by the ABPN (Bd., Dec. '77).

6. Endorsed the concept of inservice training examinations and instructed the APA Office of Education to work with appropriate organizations to develop an external evaluation program, and authorized a winter 1978 meeting to address the issue of linking inservice training assessment with Board certification (Bd., Dec. '77).

7. Voted to actively explore tripartite composition (APA, ABPN, and AMA) of the Psychiatry and Neurology Residency Review Committee (Bd., Dec. '77).

8. Endorsed the recommendation of the Reference Committee that the full Board of Trustees should review the membership survey on Board certification, after response had been received from the ABPN and returned for later approval by the Board; approved a survey on Board certification to be circulated to a sample of the APA membership (Bd., Dec. '77).

9. Voted that APA instruct its councillors on the Accreditation Council for Psychiatric Facilities (ACPF) to urge the ACPF to review the present standards for community mental health programs and make necessary modifications to ensure that high quality psychiatric care will be a significant and integral part of all community mental health programs; that APA work with AHA to urge the ACPF to move forward toward development of core standards; and that APA's councillors to the ACPF be instructed concerning the APA's position in favor of a single inspection of psychiatric facilities, to avoid multiple surveys (Bd., Dec. '77).

10. Voted to establish liaison with the Association of Mental Health Clergy (Bd., Dec. '77).

11. Voted to establish formal liaison with the Office of Human Development in regard to the proposed White House Conference on the Family (Bd., Dec. '77).

12. Voted that APA urge the American Medical Association to effect continuous psychiatric representation on the National Joint Practice Commission (Bd., Dec. '77).

13. Approved APA's cosponsoring with the National Council on the Aging, Inc., the Annual Conference on Aging to be held April 16–19, 1978, in St. Louis, Mo., at no cost to the Association (Bd., Dec. '77).

14. Recommended that the National Society for Autistic Children, the National Association of Social Workers, and the Epilepsy Foundation of America be admitted for membership in the Accreditation Council for the Mentally Retarded and Other Disabled Individuals (Bd., Dec. '77).

15. Voted to establish liaison with the American Correctional Health Services Association for a period of two years at no cost to APA (Ex.C., Feb. '78).

16. Approved APA's becoming a cooperative sponsor of the Fourth AMA National Congress on Improving the Quality of Life with Focus on the Family at no cost to APA (Ex.C., Feb. '77).

17. Authorized APA's participation in the formation of a National Psychosurgery Board; funding will be sought and provided by the appropriate agency or agencies in the Department of HEW (Bd., Mar. '78).

MEMBERSHIP MATTERS

1. Adopted the policy recommended by the Membership Committee that the appropriate district branch be notified when any member elected to Fellowship has missed three Convocations at which the member was eligible to receive the medallion and certificate, so that there can be appropriate presentation and recognition by the district branch (Bd., May '77).

2. Accepted for inclusion in the *Operations Manual* the policy that a member is responsible for dues to the district branch in which he or she is officially enrolled on the first day of January, as recorded in the Central Office Membership Division; and that, in the event of transfer to another district branch, the above-mentioned payment of dues will keep the member in good standing for the balance of the new branch's year (Ex.C., June '77).

3. Accepted for inclusion in the *Operations Manual* the recommendation that all joint membership actions, other than waiver of dues, shall become effective simultaneously in both the national APA and the district branch as of a date defined by the Central Office for implementation of the action (Ex.C., June '77).

4. Voted to approve the reduction in dues to $110 per year for members who have reached age 70 and who have been dues-paying members for at least 15 years but who have not achieved life status (Bd., Dec. '77).

5. Voted to approve requiring Life Members and Life Fellows to pay for APA publications after January 1, 1979, at a cost of $12 per year for the *Journal* and $6 per year for *Psychiatric News* (Bd., Dec. '77).

6. Voted to authorize the Membership Committee to include Continuing Medical Education requirements for membership in its processing review recommendations regarding membership status of members to the Board (Bd., Dec. '77).

7. Voted to approve the policy that the Membership Committee utilize Inactive Member and Fellow status on other than a permanent basis, that such request be addressed on a case-by-case basis, and that recommendations for temporary inactive status be limited to one year (Bd., Dec. '77).

POSITION STATEMENTS AND RESOLUTIONS

1. Approved the position statement on active treatment, pending further comments and approval by the Assembly (Bd., Dec. '77).

2. Approved the Assembly revision of the resolution of the Committee of Black Psychiatrists on affirmative action (Bd., Dec. '77).

3. Approved the position statement on abortion as approved by the Assembly and the Reference Committee (Bd., Dec. '77).

4. Authorized publication of the Report of the Task Force on Arbitrary Discrimination Against Persons with Previous Psychiatric Treatment, including the position statement in the report that had been approved by the Assembly (Bd., Dec. '77).

5. Rescinded APA's 1972 position statement on involuntary hospitalization of the mentally ill because it does not reflect the current situation, and asked the Commission on Judicial Action to prepare an interim statement for use until the new position being developed by the Committee on Psychiatry and the Law has been finished and approved (Ex.C., June '77).

PUBLIC AFFAIRS

1. Formally requested the President of APA or his designee to communicate directly with the president of the Mental Health Association in the near future to discuss the issue of hard-line tactics regarding the quality of services and efficiency in community mental health centers and other matters of mutual interest (Ex.C., June '77).

2. Authorized the President, Speaker, and Medical Director to release the Joint Commission on Public Relations' press release regarding civil rights of homosexuals, as soon as the suggested modifications are made in the document (Ex.C., June '77).

3. Voted to file a formal "fairness doctrine" complaint with the Federal Communications Commission against the American Broadcasting Company for its news close-up documentary, "Madness and Medicine" (Ex.C. June '77).

4. Authorized the Deputy Director for Business Administration to negotiate a contract with the firm of Yankelovich, Skelly and White to conduct the first phase of the Attitude Research Project, using the monies in the Public Affairs Fund that were collected for this purpose (Ex.C., Sept. '77).

5. Ratified the emergency action taken by the President, the Speaker, and the Medical Director on the submission of recommendations to the President's Commission on Mental Health Task Panel on Public Attitudes and use of the media for promotion of mental health, as requested by the Joint Commission of Public Affairs (Ex.C., Sept. '77).

6. Ratified the emergency action taken by the Vice-President, the Speaker, and the acting Medical Director to send a letter regarding the TV program, "The Other Side of Hell," to the President of NBC-TV (Ex.C., Dec. '77).

7. Ratified the emergency action of the President, Speaker, and the Medical Director to send a letter to the Procurator General of the USSR, asking permission to send a physician-psychiatrist observer to Mr. Scharansky's trial if psychiatric conditions are a factor in this trial (Ex.C., Feb. '77).

8. Authorized the President and the Medical Director to explore the possibility of APA members visiting South Africa, and to consult with the World Psychiatric Association, the Committee of Black Psychiatrists, and the Black Psychiatrists of America concerning their views on such a visit; and asked the President to obtain in writing assurances that any APA members who visited South Africa would be free to go anywhere they wished, to stay as long as necessary, and to use their own interpreters (Bd., Dec. '77).

PUBLICATIONS

1. Authorized publication of "What Is a Psychiatrist?" as revised by the Council on Emerging Issues, with minor editorial revisions and with the addition of a qualifying preface differentiating psychiatrists' treatment qualifications from others' (Ex.C., June '77).

2. Authorized the Joint Commission on Government Relations, with appropriate committee assistance, to develop an operating definition of "what a psychiatrist does" for purposes of legislation and in discussions with legislators and legislative bodies (Ex.C., June '77).

3. Approved the "Model Law on Confidentiality of Health and Social Service Records" for publication (preferably in the *American Journal of Psychiatry*, with the consent of the Editor) (Ex.C., Sept. '77).

4. Approved publication and distribution of the report of the March 1977 Peer Review Conference (Ex.C., June '77).

5. Approved the Report of the Task Force on Professional Liability Insurance for Psychiatrists, "Professional Liability Insurance and Psychiatric Malpractice," for publication as a task force report (Bd., Dec. '77).

6. Approved publishing the proceedings of the APA Symposium on Culturally Relevant Training for Psychiatrists as an APA publication (Ex.C., Feb. '77).

STAFF

1. Received the report of the Ad Hoc Committee to Search for an Editor of the *American Journal of Psychiatry* and selected Dr. John C. Nemiah from a list of highly qualified candidates. Dr. Nemiah will begin his Editorship in July 1978, when Dr. Francis J. Braceland, who has served as Editor since 1965, retires (Bd., Dec. '77).

2. Established a new position, "Associate Director for Government Relations," in the Division of Government Relations (Ex.C., June '77).

3. Approved appointment of a Personnel Advisory Subcommittee (on recommendation of the Budget Committee) composed of three persons to serve as consultants for a period of one year; their function will not include personnel management (Bd., Mar. '78).

H. KEITH H. BRODIE, M.D.

Am J Psychiatry 135:10, October 1978

Report of the Treasurer

GENERAL: This report is prepared from audited figures for the fiscal period that ended December 31, 1977. Data presented also appear in the auditor's annual report.

Attached hereto is a statement of financial condition (table 1) and pie charts (figures 1 and 2) reflecting revenues earned and functional costs for the fiscal period. This report, together with the statement and charts, will provide the membership with the information needed to assess the operation and financial condition of the Association.

FISCAL STATUS: Execution of the fiscal year 1977 budget resulted in income of $6,684,311.40 (9.4% over the budget estimate) compared to expenses of $6,177,009.65 (about 1% over the budgeted figure). This experience resulted in a surplus of income over expenses amounting to $507,301.75 for 1977. Income was strengthened by additional overhead monies stemming from APA's expanding grant/contract program, increases in advertising sales, and attendance at continuing education courses offered during the annual meeting that outstripped projections. Despite the significant increase in activity, the Association was successful in maintaining a healthy expense picture. This stems in part from the ongoing cooperation among the policy-making bodies, officers, and staff in monitoring expenses during 1977. In addition, the growing grants/contracts program allowed program expansion without the increased expenses usually connected with progress. Finally, expenses were dampened by the fact that IRS authorization for the Association to retroactively change its fiscal year period from April 1–March 31 to January 1–December 31 was not received until mid-March 1977. Therefore, new programs contained in the January 1, 1977, budget were not implemented until almost April 1977.

The surplus from operations has been placed in reserve accounts. A portion of the $507,302 surplus ($279,650) was appropriated to the Reserve for Dues Stabilization. This reserve account, currently totalling $665,700, was established in 1976 as a source of funds to offset operational costs in future years, thus delaying the need for an increase in member dues. An amount of $225,371 was appropriated to the Reserve for Future Expansion and Development. This fund, amounting to $1,980,000, is scheduled to be drawn upon heavily to meet architectural and construction costs of a new Central Office building for APA (discussed in detail later in this report). The remainder of the surplus ($2,281) was appropriated to the reserve account entitled Unrestricted Surplus, which currently shows a balance of $260,009. Total reserves have been adjusted to reflect an unrealized decline in the market value of securities over a period of many years amounting to $69,089. APA reserves show a balance of $2,836,620 as of December 31, 1977.

PROGRAM DEVELOPMENT: In accordance with a mandate from the Board of Trustees, the Association has expanded its efforts in the areas of peer review, continuing education, government relations, and public affairs. The stimulation of income sources has enabled this growth to take place within the confines of a balanced budget.

This is an edited version of the report presented by the Treasurer to the annual business meeting in Atlanta, Ga., May 9, 1978.

During 1977, APA moved ahead in the area of peer review by obtaining a government contract in the amount of approximately $678,000 to establish a retrospective system of peer review of CHAMPUS claims for inpatient and outpatient psychiatric treatment. The system is to be utilized on a national scale. One major task of the project is development of review criteria for evaluating the appropriateness of treatment.

The Office of Education increased its effectiveness during 1977 and at the same time achieved a decrease in its 1977 budget as compared with the prior year. This was achieved by a shift in emphasis from operating expenses to personnel. Although an Office of Education has existed in APA for about 15 years, its initial function was related to continuing education projects in psychiatry for nonpsychiatric physicians. Effective January 1, 1977, the Office was given responsibility for all educational efforts within APA, including undergraduate, graduate, and continuing education.

The Public Affairs Division has moved positively toward meeting a mandate of the Board of Trustees to advance the public image of psychiatry. The Division has been strengthened in terms of both staffing and operating expenses. The result is a more positive public relations program for APA, especially in the areas of press relations, development of a public affairs network, and news releases on the positive aspects of psychiatry.

The Government Relations Division has been reorganized to strengthen APA's relations with the staff and members of the Congress and of the Executive Branch. The Association has significantly increased its capacity to develop and provide constructive legislative initiatives rather than to react to measures that may be counter to the interests of psychiatry and the mentally ill. In addition, the Division has initiated relationships with other health interest groups to stimulate broader consensus support on behalf of psychiatrists and their patients.

EMPLOYEE BENEFITS: The policy of the Association seeks to maintain employee salaries approximately commensurate with those paid by the federal government (the primary employer in the Washington, D.C., area). Thus, a cost-of-living increase closely matching that granted by the federal establishment (7%) was awarded to our employees in October 1977. Other benefit costs increased due to staff expansion and inflationary pressures; however, these costs were all within budgetary guidelines.

GRANTS AND CONTRACTS: In February 1977, based on the recommendations of the Treasurer, the Executive Committee of the Board of Trustees identified the obtaining of grants and contracts to support needed programs as a top priority and authorized an expenditure of $8,000 from its 1977 Contingency Emergency Fund for the procurement of such funds. At that time, the Association was receiving monies via grants and contracts at the rate of $294,842 per year. Efforts of management, at all levels within the Association, culminated in the attainment of five grants/contracts during 1977 amounting to additional income of $881,892, for a total annual income from grants/contracts of $1,176,734. Overhead income expected from grants and contracts has increased from $16,000 projected for 1977 (prior to the top pri-

TABLE 1
Comparison of Fiscal Years 1976 and 1977

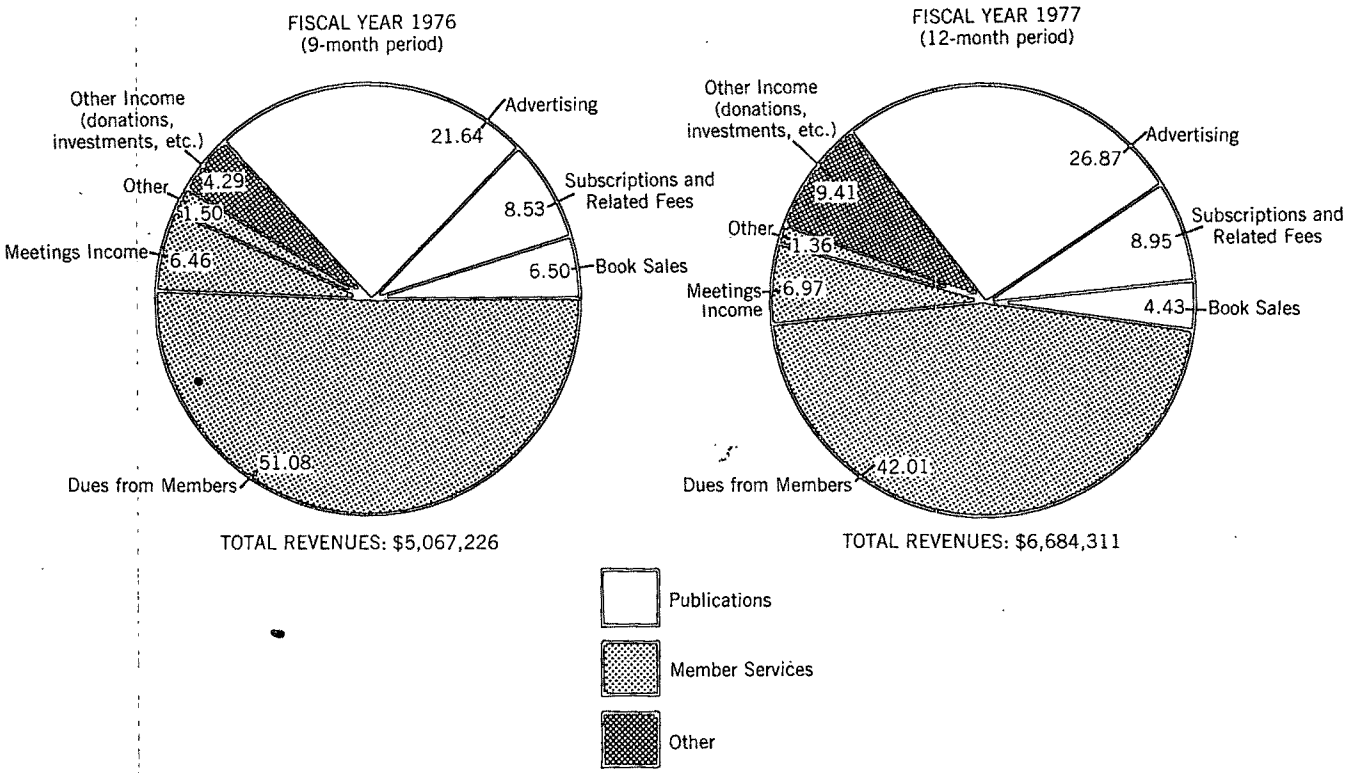
Item	1976	1977
ASSETS		
Cash and savings accounts	$ 457,620	$ 15,000
Certificates of deposit	320,000	320,000
Accounts receivable	492,203	674,893
Accrued interest receivable	29,559	38,738
Deferred and prepaid expenses	99,711	147,545
Marketable securities		
Stocks and bonds (at quoted market value)	1,023,749	1,047,442
U.S. Treasury bills, etc., short-term investments at cost	594,130	1,165,863
Notes and advances receivable from the American Psychiatric Museum Association, Inc.	1,757,085	1,757,085
Less valuation reserve	(1,757,085)	(1,757,085)
Land and buildings (at nominal value)	1	1
Furniture and equipment (at nominal value)	1	1
Total assets	$3,016,974	$3,409,483
Deduct		
Cash and marketable securities allocated from general fund to restricted fund	302,223	400,964
Total general fund	$2,714,751	$3,008,519
LIABILITIES		
Accounts payable and accrued expenses	137,464	11,954
Due to district branches	3,639	36,641
Deferred income	20,573	23,304
Reserve for stabilization of future dues	579,075	665,700
Reserve for future expansion and development	1,754,629	1,980,000
Less valuation reserve, marketable securities	(38,357)	(69,089)
Total liabilities	$2,457,023	$2,748,510
Unrestricted surplus		
At beginning of year	257,728	257,728
Net change during year ended		2,281
At end of year	257,728	260,009
Total general fund	$2,714,751	$3,008,519

ority established for grants/contracts) to $120,000 expected during 1978 (an increase of $104,000). Federal funds to support fringe benefits for employees are projected to increase from $5,000 per year to $30,000 (an increase of $25,000). Efforts to expand revenue from grants and contracts will continue in 1978 and prospects are good for continued success.

CENTRAL OFFICE BUILDING: The Association staff has now exceeded the bounds of its existing office building, resulting in overcrowded conditions in the Central Office buildings and the leasing of space at two additional sites. Also, staff working conditions are inadequate, especially during warm and cold periods, and the trend for increased costs of building operations and maintenance noted during past years continues. These problems led to an extensive evaluation of the APA buildings by an architectural and engineering firm, an assessment of the property by a member of the American Institute of Real Estate Appraisers, and an analysis of real estate opportunities for the Association in the Washington metropolitan area. These studies revealed that renovation of the existing buildings is not feasible and point to the need for APA to obtain new office space to house its Central Office facilities. These studies indicate a current need for approximately 32,000 square feet of net usable office space initially, with expansion to about 50,000 square feet of space (based on industry averages) within 10 years. The Treasurer, in conjunction with the Investment Advisory Committee and staff, conducted a study of the fiscal implications of a decision for the Association to purchase or construct its own building, at an estimated cost of $4,500,000, to house its Central Office, as opposed to a decision to lease space for this purpose. The study revealed that a decision for APA to purchase or construct its own building would result in net *income* of more than $2,000,000 over a 30-year period. This compares to *costs* of $37,000,000 if a decision were made to lease. Therefore, APA would realize an advantage of about $39,000,000 over a period of 30 years if it elects to purchase or construct its own building rather than lease comparable office space. The APA House Committee and staff have reviewed approximately 20 buildings in the Washington metropolitan area and found none that meet the needs of the Association. After reviewing over 20 available lots, it has been determined that the lot located on the northern corner of Connecticut Avenue and Hillyer Place, Washington, D.C., is suitable in terms of location and size. A sales contract for the lot in the amount of $869,220 was executed on March 20, 1978, by both the seller and APA, with the understanding that the Association would have 90 days (until June 18, 1978) to conduct additional feasibility studies prior to closing.

INVESTMENTS: The stated investment policy of the Association is to "employ sound investment vehicles affording the maximum return consonant with safety of capital, i.e., the type of investment a prudent individual would seek." As a result, the majority of the Association's portfolio (86.4%) is invested in intermediate and short-term securities. The $320,000 held in savings and loan association certificates accrued interest at the rate of 7½%, for earnings of $24,000. Savings accounts in commercial banks (which were opened in late 1976 because of low yields on government obligations) had an opening balance of $450,000. Funds were held in these accounts until the yields on government obligations became more attractive. As the rates increased, large portions of these funds were transferred from these accounts into Treasury bills. Interest earned on these savings accounts amounted to $18,600. The U.S. Treasury bills constituted the remainder of investment funds with a balance of $1,165,863 at year's end. The amounts held during the year varied between $2,300,000 and $300,000. Earnings from these vehicles amounted to over $82,500 for the period. The year just ended was a year of decline in the stock market. It is interesting to note that in 1977 the percentage of decline for the Standard & Poor's "500," and Dow-Jones Industrial Average, and the New York Stock Exchange Composite were 10.7%, 11.5%, and 17.3%, respectively. Therefore, under the guidance of our Investment Advisory Committee, our portfolio decreased its holdings in equities and invested transferred funds in more secure fixed-income securities such as bonds and short-term notes. Equity holdings amount to only 13.6% of the total portfolio. The total decline in the equities section of the portfolio was 8.2% for the year, which compares favorably with the market in general. However, it should be noted that the average gain on equity investments since the establishment of the Investment Advisory Com-

FIGURE 1
Comparison of APA Revenues, in Percents



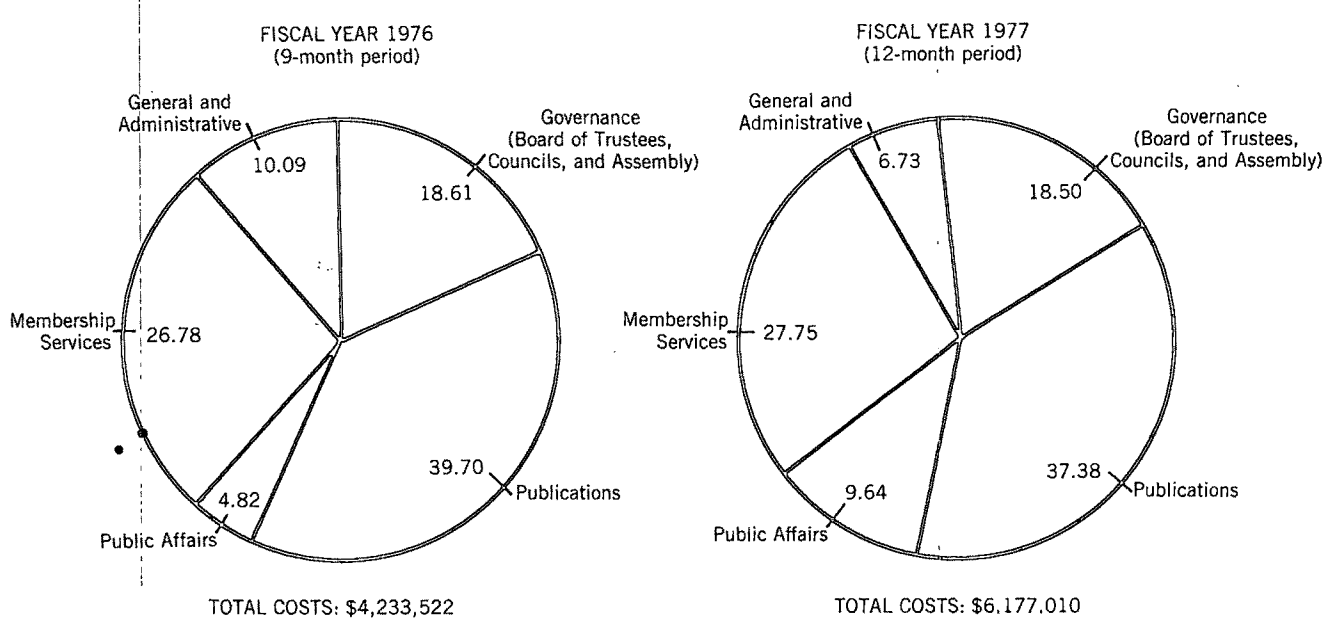


FIGURE 2
Comparison of APA Costs, in Percents

mittee (from October 1975 through December 1977) has been 15.2%. Dividends on stocks for the year totaled $17,050 and income from bonds amounted to $30,238.

PUBLICATIONS: *Psychiatric News* generated revenues of $998,804, contrasted with expenses of $841,006, for a surplus of $157,798. The revenue amount represents an increase of $407,658 over the 1976 amount. This gain stems primarily from a great increase in advertising revenues.

The *American Journal of Psychiatry* produced revenues of $874,553 and generated expenses of $948,569, for a deficit of $74,016. It should be noted that the Association levies an overhead charge to its three publications at the rate estab-

lished for indirect costs for federal grants and contracts. The overhead rate for the *American Journal of Psychiatry* during 1977 was 37.4% of direct costs. This publication showed a surplus of $137,483, excluding APA overhead charges.

The *Hospital & Community Psychiatry* journal realized revenues amounting to $295,806 and expenses of $394,357. The resulting deficit was $98,551. After adjusting for the APA overhead charge to the journal, the deficit for 1977 was reduced to $10,610.

The Association maintains approximately 90 book titles in inventory. The total revenues, net of discounts for 1977, were $266,457, which showed a modest gain over 1976 totals. The Association's publications are produced and marketed at prices which assure a return of the printing and distribution costs. The excess of revenues from sales over expenses keeps this activity on a self-sustaining basis.

VI WORLD CONGRESS OF PSYCHIATRY: APA served as host for the VI World Congress of Psychiatry, held in Honolulu from August 28 through September 3, 1977. In this capacity, the Association accepted full responsibility for the business and fiscal arrangements for the Congress. The event was successful in both professional and operational terms. Proceeds from the meeting were sufficient to allow APA to 1) donate $50,000 to the World Psychiatric Association and 2) reasonably cover the costs incurred in the planning and conduct of the Congress.

CONCLUSION: It is a pleasure to present what I believe is a very forthright and positive annual report on the fiscal activities of APA during 1977 and the financial condition of the Association at this time.

I wish to express my gratitude to the membership for entrusting me with the responsibility for the fiscal affairs of APA over the past two years and to the Assembly of District Branches, the Board of Trustees, the officers, and the Investment Advisory Committee for their support and their ongoing interest in the financial stability of the Association. Appreciation is also due to the Medical Director, the Deputy Director for Business Administration, the Comptroller, and the entire staff for their capable assistance whenever needed during the year.

CHARLES B. WILKINSON, M.D.

Am J Psychiatry 135:10, October 1978

Report of the Medical Director

IT IS A privilege to present my fourth annual report to you. I am particularly pleased to say that staff development has proceeded to a point where we can implement the goals and aspirations of our membership in a qualitatively improved manner. We are indeed a complex organization with multiple functions and perspectives. It is striking, however, that in recent years much greater consensus has been achieved regarding how we must be responsible and accountable in providing the best possible psychiatric treatment for our patients.

The Association continues to grow at the rate of approximately 1,000 new members per year, and there are distinct organizational implications of this level of growth. In my report this year, I focus on the consolidation of activities that members have requested, including continuing education, member benefits, government relations, and judicial action. In addition, APA is planning a new headquarters building which will provide an opportunity to consolidate structurally as well as functionally.

Internal consolidation of activities, to allow for management by objectives and line functioning, has led to the development of various staff committees to coordinate activities involving various staff. Examples of these committees are the Staff Committee to Coordinate the Board and Assembly and the Staff Committee on the Annual Meeting. These committees allow for a free-flowing exchange of ideas that we hope will improve the various activities that staff is involved in implementing for the membership.

This year has also brought a new coping phenomenon dealing with the multiple areas of accountability. Since September, we have been concerned with appropriate input into the preliminary report of the President's Commission on Mental Health. Now, the vital concern will be providing comments on the final report before legislation and regulation-writing.

National health insurance developments must be constantly monitored while we continue to develop data that will support the best possible psychiatric coverage for our patients. Related to this, one of the major issues on the current horizon is government pressures for medicine to be involved with voluntary cost containment.

During the past year, APA has assumed more of a proactive leadership role in developing a consortium of psychiatric education groups, in meeting and collaborating with the Mental Health Association in areas of mutual agreement, and with the American Psychological Association in attempting to define areas of agreement as well as delineating adversarial positions. Staff has spent a great deal of time working with the executive and legislative branches of government in attempting to ensure that the NIMH budget is adequate, that APA has some input into the changes being contemplated at ADAMHA, and suggesting persons to be considered for the directorship of NIMH.

APA has also assumed a growing and important role in the international arena; the outcome of the resolution presented by the Association to the World Psychiatric Association at the General Assembly in August 1978 in Hawaii will be reported to you. The APA Committee on Psychiatry and Foreign Affairs has been active in a new study, "The Emotional Aspects of the Present Egyptian/Israeli Interaction," and a group of APA members traveled to Cairo and to Jerusalem this year.

This is a capsule overview of the many activities that your staff has been engaged in; I will speak to some of these issues in a little more depth.

For historical purposes, I have asked each department and division head, and each deputy director, to prepare a detailed report on activities. This is available to any member who might wish a copy.

CHAMPUS PSYCHIATRIC PEER REVIEW PROJECT

One of our most innovative projects, perhaps with the most far-reaching implications for the field of psychiatry, began in the summer of 1977 when a contract was signed between APA and the Civilian Health and Medical Program of the Uniformed Services (CHAMPUS) to provide a peer review system that would cover the entire country. The contract provided $678,054 for operation of the project for one year, with a renewal clause. A project office was immediately established, headed by Mr. Norman Penner, and staff was assembled.

There are five specific tasks to be carried out by the APA: 1) provide a National Advisory Panel of psychiatrists to oversee the development and operation of the peer review system; 2) develop criteria (inpatient and outpatient) to be used by CHAMPUS claims processors to determine which claims go to a peer review panel; 3) identify psychiatrists willing to conduct CHAMPUS claims peer review; 4) training CHAMPUS claims processor personnel to handle psychiatric claims and case review; and 5) provide peer review. The contract provides that each case going to peer review is to be reviewed by three psychiatrists. APA will monitor reviewers' performance and reimburse them at the rate of $50 per hour.

Each district branch was asked to provide the names of at least four psychiatrists who might serve as peer reviewers. Some 300 names were received and a letter of appointment/agreement was sent to 295 psychiatrists.

In summary, the guidelines have been completed and presented to the CHAMPUS staff, the CHAMPUS fiscal intermediary staffs have been trained in the system, and some 290 psychiatrists have been assembled and are ready to begin the peer review for CHAMPUS.

Not only is there a high degree of interest in the project as evidenced by the large number of letters from members who have volunteered to serve as reviewers, but the federal employees' Blue Cross/Blue Shield plan and Aetna have asked to be kept informed about the progress of the program. There is no doubt that the project will result in a more uniform claim adjudication process nationally than is now the case, and may indeed prove to be a model for use by others.

This is an edited version of the report presented by the Medical Director to the annual business meeting in Atlanta, Ga., May 9, 1978.

GOVERNMENT RELATIONS

The division provides the interface for APA policy with the legislative and executive branches of the government, and, in addition, seeks to provide insights into and analysis of such legislative and executive activities to assist in the development of APA policy. As a result of APA's renewed commitment to improve and expand government relations activities as requested by various members and the Assembly, Jay B. Cutler, J.D., formerly Minority Counsel to the U.S. Senate Health Subcommittee, was appointed Special Counsel and Director of the Division in May 1977. During the past year the division has actively engaged the Congress on each issue that has an impact on psychiatry, ranging from national health insurance and health planning to drug regulation reform, NIMH appropriations, reimbursement for nonphysicians, and others.

One of the most important activities, undertaken in conjunction with Mr. Sam Muszynski, was ensuring that the Health Planning Law (P.L. 93-641) included mental health planning. The law has been successfully amended to explicitly include mental health planning.

In conjunction with the coalition of psychiatric education organizations, the division is actively lobbying to increase the budget for mental health manpower training in the Labor/HEW Appropriations Bill, fiscal year 1979, from $86.6 million to $108.25 million.

In all of the above, and in many more instances, APA has demonstrated proactive legislative responsibilities and is responsible for the inclusion of genetic conditions leading to mental illness as a matter for research and training under Title XI of the Public Health Service Act.

PUBLIC AFFAIRS

In August 1977, all APA members received a mailing asking for donations to support a survey of public attitudes to be under the direction of the Joint Commission on Public Affairs. Obviously this was an activity that greatly interested the membership, and more than $50,000 was donated by APA members to support the study. The survey was begun in November and preliminary results were shared with the members at a special session during the annual meeting. The firm of Yankelovich, Skelly and White, a nationally prominent research organization, conducted the survey; it is anticipated that there may be additional research or public relations programs developed on the basis of results of the research.

The division produced the first two issues of the *Public Affairs Network Newsletter*; in its first year, this network has grown to include 33 district branches and will be extremely useful in working with the news media.

The division hopes to provide accurate information about the psychiatric profession, refer reporters to experts in the field, establish more ongoing relationships between members and the media, and encourage reporting of events favorable to psychiatry in order to enhance its public image. In relation to these efforts, the division issued 10 press releases involving: APA's position on homosexuality, the Joint Information Service study on nursing homes, passage of the ERA, a protest of the ABC broadcast "Madness and Medicine," and comments on the preliminary report of the President's Commission on Mental Health.

In March, APA was informed that the National Science Foundation had awarded a grant of $37,600 to support a Symposium for Media Writers, "Research Briefings on Mental Health," to be held this summer. Mr. Robert L. Robinson and the Division of Public Affairs will work with the Joint Commission on Public Affairs in arranging for this meeting.

GENERAL COUNSEL

On January 1, 1978, Rogovin, Stern and Huge were designated General Counsel for the American Psychiatric Association. Before that, Mr. Joel Klein of that firm had served as Special Counsel. The major litigation effort of APA (other than judicial action matters) was to challenge the ABC program "Madness and Medicine." A "Fairness Doctrine" complaint was filed with the Federal Communications Commission in October, attacking the bias of—and the harm to the public created by—"Madness and Medicine." FCC staff has been actively investigating the complaint; ABC replied to the issues raised by APA in the complaint and APA also responded to the ABC document and filed additional materials, including an affidavit from Dr. Russel L. Guiss, Superintendent of Dammasch State Hospital in Wilsonville, Ore., expressing concern about the biased approach used by ABC in filming and reporting on conditions at that hospital. As yet, the FCC has not ruled on the complaint.

Mr. Klein and the firm have been quite active in advising the district branches on various legal matters, particularly those involving ethics and tax status, matters of confidentiality, and state commitment laws.

Another major activity was a legal analysis of the issues involved in setting up a body within the World Psychiatric Association to investigate and monitor abuses of psychiatry throughout the world. This analysis was used by Dr. Jack Weinberg and me at the meeting of the WPA Executive Committee in New Delhi in January. I plan to report further on the follow-up of issues relating to the WPA later in this document.

OFFICE OF EDUCATION

There has been rapid growth and development of the Office of Education under the guidance of Dr. Carolyn Robinowitz. The structure and function of the office continue to undergo major change. The office, in collaboration with the Council on Medical Education and Career Development, has been able to make great progress in the area of psychiatric education and has allowed APA to play a leadership role in the academic community as convenor, overseer, and stimulator for consortial projects from all sectors of the academic community. As part of its responsibility for all education efforts, the office has expanded its activities in the areas of undergraduate, graduate, and continuing education, and has become increasingly involved in issues related to manpower development.

The Office of Education has cosponsored approximately 335 programs for an estimated 4,606 hours of Category I CME credit. These programs have been developed primarily by district branches; the office has worked most closely with branches in New York, Massachusetts, Colorado, Washington, and the District of Columbia. Staff is also available for program consultation to district branch continuing education committees, and Dr. Robinowitz and Assistant Director Dr. Sue Quick have visited a number of branches and Area Councils during the past year.

APA continuing education will be mandatory to retain

membership, and the office will begin to inform individual members of the need to comply with the CME requirements on or before July 1, 1979. An information and recording booklet has been prepared and mailed to members; there is also a fact sheet on continuing medical education which was mailed to the entire membership. Reminders and information have also been prepared for district branch newsletters and for *Psychiatric News*.

The Office of Education was awarded a grant to hold a series of national and regional conference workshops on Educational Development for Psychiatric Educators (EDPE). These meetings are designed to stimulate development of educational planning, implementation, and evaluation skills, and have been planned through the joint efforts of APA and a consortium of psychiatric educational organizations. A national conference was held in January 1978 focusing on the topic Teaching the Resident How to Teach. There were 200 participants, and initial feedback and evaluation have been quite positive. Future planned activities include two or three regional conferences in 1978–79 and publication of proceedings and continued development of resource materials for teaching.

As the continuing education functions of the annual meeting increase, there has been greater liaison between the Office of Education, the Division of Public Affairs, and the Office of Professional Affairs in planning and implementing these activities.

Problems are related to change, increased demands, and further development of functions. During the coming year the office hopes to determine and implement policy on basic and continuing education through work with the Council on Medical Education and Career Development, develop a stronger research base in all aspects of psychiatric education, develop educational materials for the field, develop and maintain closer liaison with other staff and with outside organizations regarding government activities to ensure APA's viability, develop a closer working relationship with ABPN to develop a research base to determine the reliability and validity of the evaluation process, and to extend the close working relationships with psychiatric service and education organizations, with nonpsychiatric medical specialty societies, educational organizations, and other mental health disciplines in areas of common interest and concern.

DEPUTY MEDICAL DIRECTOR

During this past year, Dr. Donald W. Hammersley was instrumental in negotiating the contract with CHAMPUS and the Department of Defense which has resulted in the APA project alluded to earlier in this report. Negotiated primarily because of his efforts, this innovative collaboration between APA and CHAMPUS is one of the first national peer review projects undertaken by a medical specialty organization.

Working with an ad hoc committee, Dr. Hammersley and his staff planned and carried out the logistics for the Conference on the Chronic Mental Patient, held January 11–14, 1978. The conference, held in collaboration with the President's Commission on Mental Health, produced important recommendations which were presented to the President's commission and will be circulated to APA components, with a view to developing an APA policy and program for the chronic mental patient.

Under a contract with NIMH, APA has submitted a document on "Psychopharmacologic Screening Criteria," and we hope NIMH will grant permission to publish these criteria in the next revision of the *APA Manual for Psychiatric Peer Review*. Dr. Hammersley, working closely with Dr. Richard Dorsey, provided support to the panel of experts who developed these criteria as a model for a review process to identify what prescribing practices of psychopharmacologic medication should be examined in peer review.

OFFICE OF PROFESSIONAL AFFAIRS

During 1977 this office developed a brochure titled "Careers in Psychiatry" to answer the increased number of inquiries (more than 900 in 1977) concerning the practice of psychiatry which come in from high school and college students. This is a valuable information booklet that is available to anyone interested.

The Hospital & Community Psychiatry Service continues at the approximate level of last year, with slightly over 800 institutional members. The H&CP Institute, held in San Francisco in 1977, was a success and attracted more than 1,135 registrants. The focus of the meeting, "The Chronic Patient: Rights, Responsibility, Resources," provided valuable information to the Conference on the Chronic Mental Patient and to the President's Commission on Mental Health.

There has been an increase in activities in this office, as Dr. Henry Work has assumed staff responsibility for the Staff Committee on the Annual Meeting, the Staff Committee to Coordinate Board/Assembly activities, the Program Committee, the Assembly, and the Council on Research and Development. In addition, Dr. Work serves as a member of the Steering Committee for the Key Conference Recommendations.

Many liaison activities are carried out through this office; Dr. Work was recently elected secretary of the Group for the Advancement of Psychiatry and secretary-general of the American College of Psychiatrists.

OFFICE OF MINORITY AFFAIRS

Mental health issues relating to underrepresented groups continue to be the main focus of activity and responsibility of the office. In addition to providing staff support for the Council on Children, Adolescents and Their Families, and to the Council on National Affairs, the office has directed time and effort toward keeping channels of communication open between the councils and the various components in liaison activities, both within and without the APA structure. Liaison has been maintained with the American Academy of Child Psychiatry, the American Association of Psychiatric Services for Children, State Mental Health Representatives for Children, and the American Academy of Family Practice.

In addition, Dr. Jeanne Spurlock serves as the APA official liaison to the American Medical Women's Association and is a member of the NIMH Epidemiological Review Committee and the Graduate Medical Educational National Review Committee (GMENRC).

This year, a second Research Symposium was held for the APA/NIMH Fellows. There were 11 new fellowships awarded and 16 renewed; 6 Fellows completed their training in 1977. A committee of APA/NIMH Fellows volunteered to assist in the development and evaluation of a questionnaire,

to be distributed to all American medical schools, to assess mental health services for medical students.

This office has also provided support during the planning stage of the proposed Survey of Psychiatric Services for Black and Colored peoples in South Africa. This study developed from charges of alleged psychiatric abuse, the refutation of the charges during the VI World Congress of Psychiatry, and the subsequent invitation for APA to send two psychiatrists to visit South Africa, at the expense of the South African government, to look at psychiatric facilities. The visit is still in the planning stages but we are hopeful that it will occur during the coming year.

BUSINESS ADMINISTRATION

This office has now been in operation for three years. During 1977, emphasis was placed on provision of support services and fiscal resources necessary for expansion and refinement of priority programs, preparation of a balanced budget for fiscal year 1978, continued reorganization of the business activities, and planning for the development of new office space for APA.

The introduction of a new accounting machine and remittance control machine has minimized errors, reduced the time required to complete transactions, and provided for more detailed analysis and reporting of costs.

The Publications Services Division has assumed responsibility for the Publications Sales Office, providing coordination and control. In addition, this division has been active in monitoring and stimulating sales of advertising space. Sales increased by over $200,000 during 1977. A comprehensive project to evaluate the performance of the present advertising sales representatives has been initiated.

The Administrative Services Division has moved ahead significantly in the area of member benefits with the establishment, in May 1977, of the Office of Member Benefits. This office allows APA to respond to the needs of members more effectively and efficiently, and has enhanced coordination of APA components involved in insurance benefits for members.

During 1977, APA staff personnel increased from 107 to 122; 118 full-time and 4 part-time. In addition there were 13 terminations, for a turnover rate of 15%.

The Administrative Services Division also undertook the major task of revising the Personnel Policy Manual, a task which has not been done since 1963.

ASSEMBLY/BOARD

This year staff has attempted to help achieve a more viable communication system not only between the Board and the Assembly but with the district branches and area councils. In September the position of Coordinator for the Board and Assembly was established and Ms. Jeanne Robb was appointed to this post. In addition, during this past year we have attempted to provide additional staff support to the Area Councils, and various members of the staff have attended these meetings to discuss issues of concern, e.g., continuing education, government relations, and public affairs, just to mention a few.

To achieve better staff coordination, a committee was appointed with Dr. Work as chair; members include all those who provide support to the Assembly, the Board of Trustees and the Reference Committee.

In June, immediately following the 1977 annual meeting, the district branch executive secretaries came to the APA Central Office for an orientation session. This meeting was essentially one in which we attempted to provide information about how the Association operates and information about staff structure. It was a very productive meeting and will probably be repeated in 1979.

This year, steps were taken to close the communication gap between the Assembly and the other APA components, namely, the councils, commissions, committees, and task forces. During the Fall Assembly Meeting period, the Assembly liaison members to APA councils and other components met before and after the meeting to discuss how best to communicate information to the Assembly and to provide for Assembly input into issues under discussion.

AMERICAN JOURNAL OF PSYCHIATRY

After 13 years of distinguished service during which the *Journal* achieved preeminence among psychiatric periodicals, Dr. Francis J. Braceland announced his retirement as of July 1978, and the Board of Trustees selected Dr. John C. Nemiah as his successor.

In his final report to the Board of Trustees Dr. Braceland noted that in 1977 the *Journal* had experienced a larger increase in the number of papers received than in any year since he became Editor; the overall increase was 19%—1,220 papers received in 1977 compared with 1,028 in 1976. An ad hoc committee, headed by the then Editor Designate, Dr. Nemiah, met and discussed various solutions to problems occasioned by the large backlog of accepted manuscripts resulting in part from the increased number of submissions. Among the suggestions were printing one or more special issues or supplements, preferably grouped around a given topic and carrying some advertising (which would help defray costs), and adding more pages to the text section of each issue for at least a six-month period. The staff is moving toward implementing these recommendations.

PSYCHIATRIC NEWS

This is the 13th year of publication of this newspaper, which continues to provide the APA membership with broad coverage of various subjects of interest to psychiatrists. Independent studies indicate that the newspaper is probably the most widely read publication in the field.

During 1978, a new standing Committee to Review *Psychiatric News* will be appointed, reporting to the Council on Internal Organization. Staff welcomes this direct member input in determining whether *Psychiatric News* is continuing to meet APA member needs.

HOSPITAL & COMMUNITY PSYCHIATRY

During 1977, this journal continued to make progress in closing the gap between income and expenditures and steps are being taken to strengthen its financial base. There is now under way a review of *H&CP's* advertising sales to determine if the journal is currently being represented to the best advantage and if not, what steps should be taken to ensure that it is.

The magazine has been promoted primarily to psychiatric units of general hospitals, but promotional material is also

being mailed to private psychiatric hospitals, community mental health centers, partial hospitalization programs, and other groups.

H&CP is unique in that it is the only monthly journal specifically directed to professionals who work in organized treatment settings.

DATA PROCESSING DEPARTMENT

The Data Processing Department, under the Membership Division, was officially established in late April 1977. A long-range plan had been developed and APA contracted with Oceanic Enterprises, Inc. for a cost-effective turnkey system; OEI was to develop APA-owned software in a language compatible with the mini-computer that APA would eventually purchase at the end of a three-year timesharing period.

However, major internal problems developed at OEI and it was finally concluded that they could not complete the work. Increased staff technical expertise and recognition of the problems associated with dependence on an outside company to produce necessary work resulted in staff recommending the purchase of a mini-computer and custom software, which was approved by the Board of Trustees in December. During this period the department has produced and mailed 5 dues billings, processed dues payments, billed for 40 of the 71 district branches, completed specifications for all data processing requirements, and redesigned dues notice and membership card forms.

This has been a transition year; all work completed was due to heroic efforts by the staff of the Data Processing Department. It is our hope that all phases of the system will be fully operational by 1979.

LIBRARY

The librarian serves as liaison to the newly formed History, Library and Museum Committee. This group (formerly the History Commission) has prepared a "Bibliographic Guide to the History of American Psychiatry," which will be published in 1978.

A staff survey was conducted to determine the library's present information functions and future directions. As a result of this survey, a Staff Library Committee has been formed to discuss future directions of the library.

The archives special fund was terminated in 1977. However, many collections of interest to the history of APA and psychiatry in general were acquired.

In addition, archives staff have developed an overall records management program for the Association and a records management person is now a part of the library staff. During 1978, there will be an inventory and scheduling of records in order that accurate and necessary records are properly stored.

VI WORLD CONGRESS

This staff office was terminated on April 31, 1978, with the final reports on file. The meeting, held in Honolulu in August 1977, was a financial success; after all bills had been paid, APA was able to forward $50,000 to the World Psychiatric Association for use in operating the secretariat until the next World Congress. A total of 4,506 persons were registered at the congress.

MEETINGS MANAGEMENT DEPARTMENT

This department was responsible for arranging more than 200 meetings during 1977, including the fall meetings of components, Board of Trustees, Assembly, the Institute on Hospital & Community Psychiatry, and the annual meeting. In addition, the department was responsible for logistics for the VI World Congress of Psychiatry.

Also, for the first time in APA history, Meetings Management was to be involved in the logistics and staff support for the Joint Meeting of the Association with the Société Medico-Psychologique in Paris, scheduled immediately following the 1978 annual meeting. It is our feeling that staff should be involved in these joint meetings in order that the very best possible planning for our members can be accomplished.

MEMBERSHIP SERVICES AND STUDIES

The major events of 1977 were the return to the division of responsibility for dues billing other than production and mailing, problems with dues billing associated with the breakdown of the computer service, the signing of a contract with NIMH for a census of psychiatric manpower, and production of the *Biographical Directory*.

As of January 1, 1978, APA membership stood at 24,210, compared to 23,301 in 1977. APA continues to grow at a rate of approximately 1,000 new members per year.

During 1978, the division will begin the manpower study, with the hope that valuable data will be developed.

The workload of the division continues to increase. Apart from the increase in sheer numbers of members and membership transactions, a number of functions have been added to or returned to the department, and existing functions such as balloting have become more complex and time-consuming. In addition, this division will now provide staff support to the Committee on Constitution and By-Laws, and continue to do so for the Committee of Tellers, the Membership Committee, and the Ad Hoc Committee on Election Procedures.

JOINT INFORMATION SERVICE

This continues to be a very productive and important activity, jointly sponsored by APA and the Mental Health Association. One of its most important studies was published this year, *Mental Health Services for the Elderly*. Also, a report of a study of prevention services provided by community mental health centers will be published shortly. During the coming year, JIS will seek additional outside funding to support four extremely important studies: "The Effect of National Health Insurance on Psychiatric Services in Canada," "The Role of the States in Mental Health Research," and two studies intended to encourage the proliferation of psychiatric services in general hospitals.

OTHER ACTIVITIES

This past year, at the request of the Assembly and the Board of Trustees, Dr. Jack Weinberg, as the official APA

delegate to the World Psychiatric Association General Assembly, introduced a resolution that asked that WPA establish a Committee to Review the Abuse of Psychiatry, which would receive and review allegations of violation of the WPA policy regarding abuse of psychiatry and to recommend such corrective actions which seem appropriate to the WPA Executive Committee. This motion was passed by the General Assembly.

Drs. Jack Weinberg and Melvin Sabshin attended the WPA Executive Committee Meeting in New Delhi, India, in January to discuss the formation of this committee and presented a document, prepared by the APA General Counsel, dealing with the legal issues involved in setting up such a committee within the WPA. The WPA president has appointed an ad hoc committee to consider the form and function of the committee.

Also, Mr. A.B. McNulty, former Secretary of the European Commission on Human Rights, will work with a committee of three jurists who will be asked to advise the WPA on procedures to be adopted. In addition, Mr. McNulty will meet with APA and the All-Union Society of Psychiatrists (of the U.S.S.R.) to discuss issues involved in the establishment of such a committee.

APA has assumed a very proactive role in the field of international psychiatry. The APA Committee on Psychiatry and Foreign Affairs has travelled to Cairo and to Jerusalem to discuss the emotional aspects of the present Egyptian/Israeli interaction, meeting with various government and health officials.

At the request of the district branches and the Assembly, the Commission on Judicial Action has laid out a plan to assist in district branch litigation, including monies to support legal cases in the states. Guidelines have been drawn up and APA will support only those cases that have important public policy implications. For example, APA will support cases involving standards for civil commitment, the so-called right to treatment and the right to refuse treatment, and those involving important issues of patient confidentiality.

The Commission on Judicial Action hopes that this program will be of assistance to the district branches; we will report further to you next year on the outcome of the first year of experience.

APA has continued and accelerated its efforts to secure psychiatric input into the national health planning structure established by P.L. 93-641. Efforts have been focused toward seeking substantive changes in the number of federal regulations required by the act, sustaining district branch involvement with state and local health planning agencies, and recommending various legislative changes to congressional bills recently introduced to revise and extend the planning act.

Mr. Sam Muszynski, who has directed the Office of Comprehensive Health Planning, also serves as Liaison Officer for Federal Agencies. The office functions have expanded to include various additional activities with federal agencies responsible for the administration of programs that affect psychiatry including health manpower regulations required to nated APA responses to a number of issues of import to psychiatry including health manpower regulations required to implement P.L. 94-484, the Health Professions Education Assistance Act of 1976, reports and recommendations of the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, and regulatory procedures reform in the Department of Health, Education and Welfare.

As we become more active in the legislative field, it is of equal importance for APA to have input into the regulation writing process that implements the laws affecting psychiatry.

CLOSING REMARKS

We continue to make progress in our attempts to coordinate staff functions in order to provide maximum service to members.

1978 will be an active year as we respond to the Report of the President's Commission on Mental Health, providing input into any legislation that is proposed as a result of the recommendations; as we make plans to implement the new Constitution and By-Laws, if the changes are approved by the membership; as we work with the many agencies of government that impinge on the practice of psychiatry: HEW, ADAMHA, and NIMH, to name just a few. In all of these activities, we will carry out the mandates and policies of the Assembly, the Board of Trustees, and the members.

I would like to thank each of the officers, members of the Board of Trustees, officers and members of the Assembly, and all of the many members who have worked so hard to improve our organizational effectiveness.

As Dr. Jack Weinberg's presidential year comes to a close, I want to express to him our appreciation of his strong leadership and good working relationships with staff. His support has indeed made this complex, changing year a most pleasurable one.

MELVIN SABSHIN, M.D.

Am J Psychiatry 135:10, October 1978

Report of the Speaker

THE ASSEMBLY of the American Psychiatric Association celebrates its Quarticentennial at this 1978 Annual Meeting. As the twenty-fifth Speaker of the Assembly, it gives me pride and satisfaction to look upon the accomplishments of the past quarter century of "grassroots" involvement in the deliberations of our professional organization. This past year particularly has seen some milestones. I would like to enumerate some of them for you.

Perhaps our most significant organizational event is bringing to closure the deliberations about the governance of APA, and developing for presentation at this meeting and for vote of the membership in 1979 changes in the APA Constitution and By-Laws. The product developed is the distillate of extensive input from the district branches and the consequence of what was called the "Key Conference" three years ago. I look forward to the reception our membership will give this proposal when it comes to them for vote in 1979.

The Assembly has accomplished many things over the past year. We have realized a revision and updating of the Procedural Code that governs the conduct of the Assembly. We have accomplished revision and updating of the Guidelines for District Branch Officers, providing for the district branch leadership a "how to do it" handbook to ease the often burdensome administrative and organizational chores of our leaders. For the first time, district branch executive secretaries participated in a productive orientation and training session conducted by central office staff. We have seen the Assembly take the initiative in developing guidelines for caring for and serving impaired physicians, which augment and complement the position of the American Medical Association. We have seen a new relationship between the Assembly liaison persons and the APA council structure, with more forceful leadership and direction on the part of the Assembly in the councils. A precedent was established by virtue of the President-Elect consulting with the Speaker-Elect of the Assembly on APA Presidential appointments, utilizing the extensive and very satisfactory suggestions and recommendations solicited from the district branches. The Assembly Executive Committee supported the action of the Board of Trustees in obtaining a site for a new headquarters building. Engineering surveys and soil testing are in progress and an architect has been selected. A new headquarters building promises long-range cost savings and functional improvement of our Central Office activities. The position of Recorder of the Assembly has evolved into an extremely important post: summarizing, keeping track, and reporting to the Assembly action items completed; items referred to district branches for study, comment, and recommendation; or items referred to other components of APA. I am indebted to John Houck for his excellent stewardship of this difficult and extremely important task. Recognizing that this is our Silver Anniversary year, and acknowledging the importance of a sense of history in the organizational decision-making process, a historical update of the Assembly and the district branches was developed.

I would like to share with you some of my perceptions of trends within the practice of psychiatry. I see a continuing transition from theory to technology. Technology in the practice of psychiatry has differed from technology in the rest of medicine. In the general medical field, the hospital was perceived as the only location in which to apply technology, and the heightened expectations were related to magical cures. Technology did not create the cure-all that had been anticipated. The disillusionment, disappointment, frustration, anger, and further demands for a response—from government, and from the technology of today's society—were the inevitable result. Technology in the practice of psychiatry operates in a direction different from that of general medicine in that psychiatry has decreased rather than increased its dependence on the hospital. The psychodynamics of the 1940s were overrun by the psychopharmacology of the 1950s and the heightened expectations of the 1960s, and the community mental health center movement expanded psychiatry into a "quick fix" for broad social problems. I hope we are at the tail end of the rebound antimedical and antipsychiatric attitude of the 1970s.

There is a seductiveness in nostalgia. We wish that we could return to the physician-humanist model of the early part of this century. It is my hope, and it will be my effort, to see the new psychiatrist modeled as a physician-humanist-scientist, who feels comfortable in the arts *and* the sciences and can provide clinical and program guidance for patients who are unable to cope with life crises or whose structure of character and personality cause them to abrade the social fabric of our communities and who may need highly technical intervention, as well as those with major mental disorders, for whom compassion, understanding, and human care must serve as we strive for greater scientific knowledge of these illnesses so painful to our patients and their families.

This past year saw the United States as the host country for the meeting of the World Psychiatric Association. We have concerned ourselves with the "rights issues" that resulted from this meeting. There was also much scientific and technological information and knowledge presented in Honolulu that can be helpful to us in program designs. We find that retrospective studies about the causes and results of mental disorder are still in process and are telling us the same things cross-culturally. The expectation that "controlled cultures" would enable follow-up and provide information not revealed in the United States has not borne fruit. Prospective studies are still in the "maybe" stage. The Third World countries appear to place a great emphasis on the use of social policy as a means of influencing health and controlling disease. Thus far what we have seen is that death-preventing technology has been successful; however, disability-preventing technology has not. We also have seen that, cross-culturally, primary prevention as a relevant and successful technology is not in view.

Observation on a lighter side about our activities leads me to make a few irreverent comments about our annual meeting. Having participated in some 15 of these annual meetings in my 20-plus years as an APA member, I must say that the

This is an edited version of the report presented by the Speaker of the Assembly of District Branches to the annual business meeting in Atlanta, Ga., May 9, 1978.

APA annual meeting seems to be the intellectual equivalent of a fundamentalist revival. We attend, purge ourselves of guilt over neglect and inaction, and return to our clinics and practice doing the same things we have been doing. We see an ecumenical embrace of indulgences in the form of CME credits, in addition to the traditional tithing by a dues payment and fees. One thing CME has done is to teach doctors to be "creative" when completing their CME forms. Whether the annual meeting will survive as an APA institution remains to be seen. The American Medical Association, the nation's largest professional group, is abandoning its huge annual meeting and replacing it with a series of smaller regional meetings directed primarily toward meeting continuing medical education requirements. The bell you hear tolling may be blown by the winds of the Equal Rights Amendment.

I could not end without some commentary about the most important public mental health event in the past two decades—the establishment of the President's Commission on Mental Health. Although modest in its service recommendations, the report recognized and addresses great needs in research, and puts focus on the oft-neglected group of patients with major mental disorders. Let us be ready for a real surge of progress as the seeds of this report take root in the capital of this country and its recommendations are implemented in our programs throughout the land.

Participation in the affairs of APA as one of its elected officers, although exhausting, is a very rewarding personal and professional experience. I thank you for the opportunity to serve.

DANIEL A. GRABSKI, M.D.

Am J Psychiatry 135:10, October 1978

Report of the Speaker-Elect

THE ASSEMBLY has been fortunate in its leadership during the 25 years of its history, and it is an awesome honor to have been chosen as its Speaker in these troubled times. The past several years have witnessed many changes in the organization of the American Psychiatric Association, and much of what had been thought to require constitutional revision has already been effected through less drastic modifications of procedures. The net result has been an amicable balance between the powers of the Assembly and the Board of Trustees, whose continuing attentiveness to the spirit of the Key Biscayne Conference can only be admired by those who view structure as a means to an end rather than an end in itself. Whether the current alliance between those two bodies will be enough to secure the goals of APA remains for the membership to decide. I hope that whatever decision is made will be on the basis of an informed membership, and that every effort will be made—at every level of APA—to look at the implications of the proposed changes in the Constitution.

It would be unfortunate, however, if we were to allow ourselves to focus exclusively on matters of internal organization. Now, more than ever before, we must grapple with external pressures and demands, and we need to come to some consensus on the host of policy issues that confront us. Any report on how psychiatry is faring at the moment in the arena of public policy might best be entitled "Notes from the Firing Line." Although it seems that only yesterday we were riding a strong wave of acceptance and enthusiastic support, the wave appears to have broken over our failure to fulfull the expectation we had generated in our admirers. Many of yesteryear's allies seem to have become this year's adversaries, now claiming not only that they do the same things we have always thought of as our functions, but even that they do them better.

The trail that we blazed through the mental health forest has become an overused expressway. We no longer enjoy exclusive rights of passage; quite the contrary, we are often challenged when we try to pass through the entrance turnstile and are asked to prove why a psychiatrist is necessary to do any of the things that have been traditional parts of our daily practice.

In the face of these countless skirmishes at the periphery, it is easy to lose sight of the central battle plan: to ensure the availability of a full range of appropriate psychiatric treatments for those who need them.

Several major obstacles to the attainment of that end can readily be identified. Often overlooked is one that is endemic to American society, where competence and achievement are revered and anything less is disavowed. As Norman Dain points out (1), this has meant that mental health reformers have generally deserted the objects of their original munificence when the "saved" patients are found to remain silent and inactive, refusing to assume the power wrested for them and seemingly unable to group themselves into a dependable and identifiable constituency for their rescuers.

We have our own brands of reformers today, and they appear in two main guises. One is the antiscience theorist, who argues that since most illness is socially induced, there is at best an expensive "window-dressing" role for medical science in the prevention or treatment of disease; that medical intervention only upsets the natural balance, which is more suitably maintained by naturopaths or other health cultists; that medicine fosters survival of the *un*fit and thereby endangers the very society it would treat; and that twentieth century treatments harm more often than they help.

Not radically different in their conclusions, and sometimes even more abrasive in their methods, are the second brand of reformers, the consumer advocates. They distrust the establishment, bureaucracy, and professionalism (which they view as the cornerstone of the health "industry"). In psychiatry, consumerism has focused on the issue of civil rights—the right to treatment, the right to refuse treatment, informed consent, commitment procedures, etc. In APA's Legislative Newsletter of March 6, 1978, I commented at length on the first chapter to emerge from the Mental Health Legislative Guide, which was published in the July-August 1977 issue of the *Mental Disability Law Reporter* as "Proposals for Change—Civil Commitment." At this point, I would only remind you of some of the more distressing proposals as an illustration of the dangers that threaten not only the profession, but even more lethally, our patients. Throughout the document, the major thrust is that the psychiatrist and his clinically based opinions are not to be trusted, and that the patient must be protected at every turn of the road by a lawyer, no matter how costly, cumbersome, traumatic, superfluous, or irrelevant his solicitous ministrations might be. The proposals ignore the patient's psychiatric condition to shepherd him through a maze of adversary proceedings, court hearings, and treatment review committees that would build a system of mandated malignant neglect. While the psychiatrist will not be allowed to testify at the time of commitment about possible dangerousness to self or others (because psychiatry has not demonstrated its competence in this area), the psychiatrist nonetheless will be asked to make such a prediction at the time of release. The proposals would allow all sorts of nonmedical personnel to be involved in treatment decisions; they advocate such intimate and restrictive involvement in clearly clinical (and not legal) issues to raise the specter of nonmedical committees ultimately deciding, by simple majority vote, what dosage of what drug may be given to what patient, at what frequency, and for what period of time. Beginning with the stage of preliminary examination and extending through the period of hospitalization and recurrent treatment reviews, the proposals require a massive dispersal of professional and other personal information to those who have neither a legitimate interest in some of the data nor a capacity to utilize them. The proposals obstruct access to treatment and destroy all possibility of continuity of care. They would transform the doctor-patient relationship into an adversary process that strips the physician of all power to make clinical decisions. They invite nonphysicians to define the specifics of treatment while they relegate the medical professional to an adjunctive role where his major function is to prepare reports for the

This is an edited version of the report presented by the Speaker-Elect of the Assembly of District Branches to the annual business meeting in Atlanta, Ga., May 9, 1978.

scrutiny of the judiciary or other reviewing authorities. The proposals' preoccupation with the mechanics of monitoring the medical profession bespeaks a reckless disregard for the welfare of the patients they claim to protect.

Distressing as such reforms might be, we must recognize that the biggest reformer of them all is the government. We know only too well that the federal government pays for an ever-increasing proportion of medical care in the United States, and it is demanding more and more control over what it pays for. What at first was a bothersome overemphasis on cost and productivity has become an intrusion by the government into professional decision-making. Costs can always be cut by shrinking the system, and that the government is clearly trying to do. But must we stand idly by if it goes on to destroy the system?

In order to deal with a society that may have good reason to distrust the establishment, in order to gain access to the architects of public policy, in order to send our message to the molders of public opinion, psychiatry must be able to articulate some concrete positions and policies that will have meaning for those we want to reach—the government, the legislatures, the media, and the citizenry.

I have already indicated how I would phrase our overall goal, viz, ensuring the availability of a full range of appropriate psychiatric treatments for those who need them. That goal can, I believe, be broken down into four major subdivisions, within each of which occur the specific, concrete questions we must be prepared to answer. Those subdivisions are as follows: 1) the kind of treatment given to those who need it, 2) who is to give the treatment, 3) where will the treatment be delivered, and 4) how will treatment be paid for?

This is hardly the time to discuss all the concrete issues contained within those subdivisions. Their very multiplicity constitutes one major problem we face; an equally important one is that any answer we might agree to give to one question will significantly affect the answers we can legitimately give to others. Let me show you what I mean.

As many of you know, it has long been my contention that we in APA have failed to define our role as physicians. In attempting to define what psychiatry is, we have often listed all the skills that the aggregate of individual psychiatrists might have. Having labeled those skills as psychiatric, we have argued that whatever is done by a psychiatrist is medical (and therefore compensable under medical insurance, to cite one application of the argument). Perhaps because we have been reared in a tradition of circular reasoning, we have also argued that since those skills are medical by definition, they cannot be practiced by anyone else.

Let us pretend that somehow we manage to break out of the circle, that as a group we agree to define what it is that the physician part of us contributes to the mental health field, and to recognize that some of the things a psychiatrist does by tradition are not, per se, medical.

By agreeing among ourselves on what a psychiatrist is, we would have answered one of the specific questions under the heading, Who is to give the treatment? In so doing, we might find that we had also answered one of the questions about how it will be paid for, in that we might find that third party payers would drop their discriminatory approach against psychiatric patients once we defined their discipline in more clearly medical terms. But at the same time we would soon learn that those among us who espouse a social systems, or ecological model of mental illness would feel betrayed. We would also have to recognize that such a step would put most of us in a position of practicing only part-time as physicians who treat the mentally ill, and the rest of the time as psychotherapists or counselors who deal with a variety of headaches in living in much the same way as other professionals and paraprofessionals within the broad field of mental health. We can also predict that by narrowing the definition of what is medically oriented psychiatry, we will have freed up the medical potential of currently practicing psychiatrists. Their medical skills can now be channeled into the void that would otherwise have required an influx of new psychiatrists.

If that were true, it might be possible to say in addition that training funds could be deployed more profitably in other areas, such as research or direct patient care. What would happen then to training programs whose ability to self-destruct seems no more remarkable or dependable than that of our own committees and task forces? And if some programs were to be eliminated, who would decide—the government, which funds them; the training directors, who run them; the residents, who use them; or the patients, who will buy their products?

As you can see, each answer is but a prelude to more difficult questions, and now you will also understand why I characterized my election to this position as an awesome honor. I can only trust that I will have your support as I continue to raise these issues before the Assembly and the Board of Trustees, and I hope that I will have your help in doing battle with the forces that would deny our patients the treatments they need.

ROBERT J. CAMPBELL, M.D.

Am J Psychiatry 135:10, October 1978

Report of the Membership Committee

THE APA MEMBERSHIP COMMITTEE met for two and a half work-filled days, October 26–28. The first two days were spent with the processing of the various membership and fellowship actions and policies as required by the Constitution and procedures established by the Board. A joint meeting was held with the Assembly Membership Committee to consider policy matters of concern to both committees. I would like to discuss some of the items requiring Board action as part of my report.

The most difficult and sensitive task of the committee is the review of and recommendations concerning Fellowship nominations. This year the committee reviewed 224 nominations and has recommended 124 to the Board to be made Fellows. The percentage of committee approvals was down this year (55% versus 66% in February 1976 and 73% in October 1976). I am at a loss to explain this phenomenon. This year's committee was perhaps more deliberate than previous committees; however, I do not believe the standards changed—some members reviewed by previous committees were again nominated for Fellowship. The committee did feel that district branch screening was generally more lax this year and certainly more erratic. A number of district branches presented large numbers of nominees who had been very poorly screened. Several of these district branches used to do better and thus contributed greatly to the decline in the number of nominees recommended. A breakdown by district branch of nominations versus passed for 1976 and 1977 shows that if those district branches which passed 25% or less but nominated two or more candidates were removed from the totals, there would then be a much more "normal" pass rate of 62%.[1] Perhaps the fact that there were two Fellowship reviews last year introduced an additional aberration, i.e., a relatively depleted pool of eligible nominees. These matters were discussed in the joint meeting with the Assembly Membership Committee.[2]

The committee deferred 18 requests for advancement of at-large members. This was due only to the lack of necessary information regarding the candidates. Since the Membership Committee has the sole responsibility for assuring that these members meet the requirements for APA membership, the committee decided that it should have more complete information, including three references, certification of satisfactory completion of residency; and proof of licensure if required by the Constitution. While recognizing that gathering more information on persons requesting advancement to Membership-at-Large status will require additional staff, the committee felt that approving these advances with less information would be abrogating its responsibility.

In joint session with the Assembly Membership Committee, there was an extensive discussion with Dr. Robinowitz of the implementation of continuing medical education requirements. We were impressed with the outstanding work being carried out by Dr. Robinowitz and the staff of the Office of Education. In the course of the discussion, the question of the role of the Membership Committee in enforcing continuing medical education requirements was raised. There was a general consensus that the Membership Committee would be involved under its mandate to review and

make recommendations to the Board of Trustees on issues of membership; however, we felt clarification is needed. It seems appropriate that the Membership Committee should review and make recommendations in those cases where membership status is to be affected by failure to meet continuing medical education requirements as it does now when a member fails to pay dues or meet other requirements of membership. Although this issue will not be pressing until 1979 or 1980, the committee would appreciate the Board's clarification of policy now so the necessary procedures can be established.

A final item brought to the Board of Trustees for policy consideration was the issue of reduced/excused dues for persons temporarily unemployed or employed only part-time. This problem seems to pertain primarily to women members who take time off from their practice for purposes of pregnancy and/or child-rearing; however, it also applies to a wide array of other special situations, one or two of which come to the attention of the Membership Committee each year.

The constitutional membership category of Inactive Member or Fellow has, in the past, been used only for those Members or Fellows with severe, permanent disabilities. Concern was expressed that should it be used otherwise, many frivolous requests for inactive status would arise and it would be difficult to assure that the member return to full dues-paying status when the reason for inactive status was no longer operative. However, it was also generally agreed that situations do arise wherein there is a legitimate reason for a member to become temporarily inactive and he/she should be able to do so without resigning membership completely.

The Board of Trustees approved two policy items at their meeting on December 10, 1977: 1) the Board of Trustees vests in the Membership Committee the responsibility to include continuing medical education requirements for membership in its processing, review, and recommendations regarding membership status of members to the Board; and 2) the Board of Trustees approves the policy that the Membership Committee utilize Inactive Member or Fellow status on other than a permanent basis, and that recommendations for temporarily inactive status be limited to one year.

JOHN R. EVERS, M.D.

Am J Psychiatry 135:10, October 1978

Report of the Committee of Tellers

THE COMMITTEE OF TELLERS met on March 9, 1978, at APA headquarters to certify the results of the 1978 election. Ballots had been mailed on January 30, 1978, at the direction of Dr. Melvin Sabshin to 22,421 eligible voting members. Sixty-eight undeliverable ballots were deducted from that number; the final number of eligible voting members was 22,353; 13,704 ballots were returned and included in the final vote tally (61.3% of the eligible voting members).

The Committee of Tellers acted on questionable ballots that had been held for their decision. The tellers also verified that all candidates for the 1978 election had certified the accuracy of their submitted biographical information and that all candidates had submitted the required statements of compliance with election guidelines.

The Committee of Tellers certified that the following individuals were elected to office: Alan A. Stone, M.D., President-Elect; Lewis L. Robbins, M.D., Vice-President; Charles B. Wilkinson, M.D., Treasurer; and Henry B. Brackin, M.D., Area V Trustee.

The Committee of Tellers further certified that in two offices, Trustee-at-Large and Area II Trustee, no candidate had obtained the mandated 40% plurality of the votes cast, as required in the *Operations Manual* of the Board. A run-off election between the top two candidates was held; Dr. Gene L. Usdin is now Trustee-at-Large, and Dr. John A. Talbott is Area II Trustee.

The Committee of Tellers certified that the two referenda (petition to demand a moratorium on the ABPN oral examinations and petition on convention sites and the Equal Rights Amendment) were defeated; the percentage of those in favor of each petition did not meet the requirements contained in the Constitution and By-Laws for adoption of referenda.

LOUIS F. RITTELMEYER, M.D.

This is an edited version of the report presented by the Committee of Tellers to the annual business meeting in Atlanta, Ga., May 9, 1978.

Report of the Committee on Constitution and By-Laws

THE COMMITTEE ON CONSTITUTION AND BY-LAWS (CCBL) was very busy this year. Numerous recommendations and referrals were received from several components of the Association. These were reviewed and studied, and then recommendations were made to the Assembly and to the Board of Trustees. The recommended amendments to the Constitution and By-Laws were approved by the Assembly and the Board of Trustees for reading to the membership at the annual meeting in May 1978 and placement on the ballot in 1979 (see appendix 1). In keeping with Article IX, Paragraph 3, of the Constitution, and Chapter Fourteen, Paragraph 1, of the By-Laws, they will be disseminated to the membership prior to January 1, 1979.

The CCBL, the Assembly, and the Board recommended the passage of these amendments. It is understood that if the membership approves the proposed Joint Conference Commission Constitution and By-Laws (JCC), these amendments, if approved by the membership, will be incorporated in the new Constitution and By-Laws. If the JCC document is not approved by the membership, these amendments, if approved, will be incorporated in the present Constitution and By-Laws.

The CCBL reviewed the JCC document[1] during its stages of development over the past year. This was in keeping with the responsibilities of the CCBL as outlined in the Constitution and By-Laws and the *Operations Manual*. During the Fall Committee Meetings the CCBL spent much time going over the document and making numerous recommendations to the JCC. These were taken into consideration by the JCC. In March 1978 a final review was made prior to the JCC presentation to the Board of Trustees in April 1978 and to the Assembly at the annual meeting in Atlanta and placing on the ballot in 1979.

The full minutes of the meetings of this committee are available to the membership of the Association, and any member is welcome to read them. The CCBL was unanimous in its recommendations of the proposed amendments and the recommendations to the JCC. There is a minority report in the minutes of the fall meeting, which expresses opposition to the recommendation that the committee recommend the petition document to the Assembly and the Board. The petition document was later withdrawn. The minority report also recommends that the functions and rules of the Assembly be more clearly spelled out in the Constitution and By-Laws rather than in the *Procedural Code* or *Operations Manual* and expresses opposition to the change in governance as proposed in the JCC document.

The proposed amendments are summarized as follows:

1. Constitution, Article II, and By-Laws, Chapter One, Section 9. This is proposed to create a new category of "Life Associate Member." The APA Membership Committee has found situations in which the absence of this category has been a problem and has recommended this amendment.

2. By-Laws, Chapter One, Section 3. After approving the requirement for CME it was realized that there would be situations where there should be an exemption from this requirement. An example would be a member who has retired or dropped out of active work for some other reason. This proposed amendment would provide for the Board to have discretion in this area.

3. By-Laws, Chapter One, Section 7. The Membership Committee studied the time requirement for advancement from General Member to Fellow and felt the limit should be raised from five to eight years.

4. By-Laws, Chapter One, Section 8, and Chapter Eight Section 6. For some time studies of the fiscal matters of the Association have shown that a problem is developing because of the increasing number of members reaching "Life" status. At the same time there seems to be a leveling off of the increase in new members each year. With the previous rapid rise in membership there will be more new Life status members; also, many members now reaching this level are still actively working. After much study by several components of the Association, it was felt wise to extend the time for a member to reach Life status, and with final approval of the Board, it was decided that a member will reach Life status in his or her category when the sum of his or her years of active membership in the Association and his or her age adds up to 95 (the "95" formula). By interpretation of the Constitution and by authorization of the Board this will not affect the present status of any member who has already reached Life status.

5. By-Laws, Chapter One, Section 12. The original section on inactive status was not clear; the proposed amendments on the "95" formula raised the question of a possible difference between an Inactive Member whose years in that status would not count toward the "95" formula and a "waiver of dues" member whose years in that status would count. The specific situations for these two categories would be spelled out in the *Operations Manual*.

6. By-Laws, Chapter Eight, Section 5, and Chapter Nine, Section 1. With the changes in the election procedures over the past few years, the Central Office staff has found an increasing problem in submitting the required material before the publishing deadlines for *Psychiatric News* on the ballots. This includes biographical data, position statements, photos, etc. Moving the deadline back from December 15 to December 1 will allow two months for the gathering of petition signatures, data, etc.

The committee appreciates the cooperation, requests, and recommendations of the various components of the Association and the review, study, critiques, and approval of these amendments by the Assembly and the Board of Trustees.

I wish to thank the members of the committee for their hard work, understanding, time, and willingness to work for a solution of the problems. The minority report outline above was well written and will be valuable to the membership in its deliberations.

W. PAYTON SCOTT, M.D.

This is an edited version of the report presented by the Committee on Constitution and By-Laws to the annual business meeting in Atlanta, Ga., May 9, 1978.

[1]The JCC document will appear in full in the October 2 issue of *Psychiatric News*.

APPENDIX 1
Proposed Amendments to the APA Constitution and By-Laws

The proposals that follow were received within the 60-day deadline before the annual meeting and were presented at the annual business session. They will appear on the ballot in March 1979.

Note: The following changes in type style indicate the kind of change proposed in the Constitution and By-Laws: 1) italic = proposed additions to the Constitution and By-Laws (e.g., "by resolution of the Assembly"*), and 2) brackets = proposed deletions from the Constitution and By-Laws (e.g., "may originate [either] . . .").* *Articles and sections of the Constitution and chapters and sections of the By-Laws that are not listed here have not been subject to any proposed changes.*

THE CONSTITUTION

ARTICLE III. MEMBERS

There shall be the following categories of membership: Life Fellows; Fellows; Life Members; General Members; *Life Associate Members*; Associate Members, Members-in-Training; Provisional Members; Distinguished Fellows; Honorary Fellows; Corresponding Fellows; Corresponding Members; *Inactive Fellows*; and Inactive Members, as defined in the By-Laws.

THE BY-LAWS

CHAPTER ONE. MEMBERS

3. To maintain membership in good standing all members, *except as exempted by the Board*, are required to participate in continuing education according to the standards of the Association.

7. Fellows shall have been General Members for at least [five] *eight* years and shall have made a significant contribution to the field of psychiatry. At its discretion the Board, upon recommendation to the Membership Committee, may waive the requirement for [five] *eight* years as a General Member. The criteria and procedures for selection and nomination of General Members for Fellowship shall be established by the Board and the Membership Committee and shall apply uniformly for all District Branches.

8. Life Fellows and Life Members shall be those in their respective categories [who have had 30 years of active membership in the Association.] *whose years of active membership in the Association plus age at the start of the fiscal year shall equal 95.*

9. Life Associate Members shall be those Associate Members whose years of active membership in the Association plus age at the start of the fiscal year shall equal 95.[1]

[12] *13.* Inactive [Members or Fellows] *members of any category* shall be those whom the Board has, for sufficient reason, excused from paying dues.

Members of any category who are placed in inactive status by the Board shall be excused from paying dues and shall not receive credit toward the "95" formula while that member is in inactive status. Active members may be granted waiver of dues by the Board for sufficient reason, and such members shall receive credit toward the "95" dues exemption formula for those years that the member is in the dues waiver status.

CHAPTER EIGHT. PRIVILEGES AND RESPONSIBILITIES

5. The voting membership may initiate referenda or change an action of the Board by the following procedure: A petition signed by at least 200 voting members shall be submitted to the Secretary no later than December [15] *1* to be voted on in the mail ballot in the following year. A statement from the petitioners setting forth the reasons for the action and a statement from the Board shall accompany the ballot. A simple majority of 40 percent of the eligible voting members shall be required for approval.

6. Every Fellow, General Member, Associate Member, and Member-in-Training shall pay both dues and assessments as determined by the Board and the District Branches. All other categories of membership shall be exempt from paying dues to both the Association and its District Branches. *A dues paying member shall be exempt from paying such dues when the sum of that member's years of active membership in the Association plus the member's age at the start of the fiscal year shall equal 95.*

Such dues will include amounts allocated to subscriptions for the *American Journal of Psychiatry* and for *Psychiatric News*. The membership application shall contain a provision for allocation of a specific portion of the dues to pay the cost of periodical subscriptions to these publications. *Dues exempt members shall pay a reduced subscription rate for these publications if such members desire to receive them.*

CHAPTER NINE. VOTING

1. Nominations for national office except that of Area Trustee shall be made by: (a) the Nominating Committee; or (b) by a petition signed by 200 or more members eligible to vote. Nominations for Area Trustee be made by: (a) procedures established by the Assembly; or (b) by a petition signed by 50 or more members of that Area who are eligible to vote. Nominating petitions must be filed with the Secretary before December [15] *1* of the year immediately previous to the one in which the nominee would be elected.

[1]If approved, this will become new Section 9; sections now numbered 9–12 would be renumbered 10–13, respectively.

Report of the Joint Conference Committee on the Key Conference Recommendations

ONE OF THE fundamental propositions emanating from the Key Conference held in March 1975 was that the Assembly become the policy-making body of the Association. Following the Key Conference, the Assembly and the Board established a series of components that have worked in concert to study a variety of organizational models and to prepare constitutional revisions that would implement the transfer of this responsibility. Early models presented bicameral systems that posed both legal and efficiency problems.

The Joint Conference Committee on the Key Conference Recommendations (JCC) has prepared an organizational model that is incorporated in the proposed Constitutional revisions. The JCC believes this model to be the best practical way to achieve the transfer of the management of the Association to the Assembly. Although this model is unicameral, checks and balances are provided for in a variety of ways, including the establishment of an Executive Board that is nationally elected by the membership. The JCC neither recommends nor opposes this change in governance but endorses this model should the membership wish to achieve the transfer of policy-making responsibility to the Assembly.

In October 1977, the Assembly voted to approve the JCC model for reorganization and to recommend it to the Board of Trustees for consideration and further action. In November 1977, the Reference Committee endorsed the recommendation of the Assembly. In December 1977, the Board of Trustees voted to present the Constitutional revisions prepared by the JCC to the membership at the 1978 annual meeting so that the amendments to the Constitution could be included on the ballot in 1979. The Committee on Constitution and By-Laws reviewed these amendments to ensure that they are in proper order. The membership will decide in the 1979 election whether the Assembly should assume the management of the Association.

COMPARISON OF PRESENT AND PROPOSED GOVERNANCE SYSTEMS

Referral and Reporting Processes

APA's annual cycle of activities is essentially from May through April. At the annual meeting in May, new officers and members of the Board and the Assembly assume their duties; changes occur in the composition of the Board, Reference Committee, and the councils and their components, as well as in the composition of the Assembly, its Executive Committee, the area councils and the district branches.

Recommendations for action or study come from both within and outside APA and may come to the Board and Assembly throughout the year. Internally, proposals for action or study may come from individual members, components of the Board (committees, commissions, councils, task forces, etc.) or components of the Assembly (district branches, area councils, Assembly or local committees and task forces, etc.). Externally, there may be pressures from legislation in process or enacted, requests from other organizations, and national or international trends and activities.

Proposals for action or study that are processed through the present governance system normally follow an established referral and reporting back process; if emergency action is needed, there are ways to expedite the process, including the emergency mechanism that involves the President, Speaker, and the Medical Director, together with appropriate consultants.

Present System

Board structure. Referrals to and reports from councils and their components are handled via the Reference Committee. Constitutional committees, ad hoc committees, and other special components have direct referral from and reporting to the Board.

Assembly structure. Referrals to and reporting from Assembly components (area councils, district branches, committees and task forces of the Assembly and counterpart committees and task forces of the area councils and district branches) are handled directly by the Assembly and its Executive Committee.

Interfaces. The Speaker is a member of the Board and its Executive Committee; the Speaker-Elect is a member of the Reference Committee. They report the recommendations of the Assembly to these bodies and report their actions to the Assembly. Each council has an Assembly liaison assigned who reports the activities of the council to the Assembly. There are some Assembly liaisons to components of councils. There are also joint commissions or conference committees that report to both the Board and Assembly. A recommendation coming to the attention of the Assembly or the Board in May can be immediately referred to each other since both bodies meet during the annual meeting. Issues may be studied at the same time by Assembly and Board components, or reports and recommendations may be studied when going through the approval process, i.e., by councils and components as well as area councils and district branches or subordinate components thereof.

Thus, in the present system, there are two organizational structures that serve for referral and reporting back with some interface and concomitant study throughout the annual cycle of APA activities.

Proposed Governance System

The Assembly would meet in May and December; the Executive Board (with all of the powers of the Assembly between meetings of the Assembly) would meet approximately four times during the course of the year.

The Executive Board would receive reports from the Reference Committee (which would also collate the reports of the nine councils and their components) and from the Constitutional committees, commissions, and special components. The Executive Board in turn would serve a triage function for the Assembly. It would act on some reports within policy previously established by the Assembly; other reports would

This is an edited version of the report of the Joint Conference Committee on Key Conference Recommendations to the annual business meeting in Atlanta, Ga., May 9, 1978.

be referred to other components for further study, recommendations, or action. In those instances when the Executive Board required policy elaboration, modification, or clarification, it would seek it from the Assembly. All actions of the Executive Board would be reported to the Assembly for ratification.

The Assembly would receive reports from two sources. The Executive Board would report to the Assembly as outlined above. The other source would be the area councils (which would also collate district branch reports). The Assembly Agenda Committee would receive all reports to the Assembly in order to organize them for consideration by the Assembly and generally facilitate the agenda process.

Thus, there would be one governance system for referral and the implementation of all Association component reports, namely the Assembly and its Executive Board. An important check and balance would be the ability of the Executive Board to delay the implementation of a policy decision by the Assembly until the next meeting of the Assembly. The Executive Board would not have the power to further delay or obviate a decision by the Assembly. The President, Speaker, and Medical Director could take emergency action when necessary.

Policy and Management

Assembly and Executive Board. The proposed governance system assigns ultimate responsibility for priority and policy decisions to the Assembly, a broadly based body with representatives who are close to their constituents, both personally and geographically, and who are accountable to them through a recall process. An Executive Board, including geographic representatives derived independently of the Assembly system, would exercise all of the powers of the Assembly in the interim between meetings of the Assembly but would report its actions to the Assembly for ratification. There would not be a Board of Trustees or an Assembly Executive Committee.

Board of Trustees and Assembly. In the present system, the Board of Trustees has the right and responsibility for policy-making decisions and management, with its Executive Committee assigned this power between meetings of the Board. Increasingly, the Assembly has played a strong role in policy-making decisions, since all position statements of the Association must be approved by both the Board and Assembly. In addition, at the annual business meeting the Assembly may by two-thirds majority vote reverse an action of the Board.

Components

Under the proposed system, components of the Association would primarily serve to aid the Assembly in its policy-making function and the Board in carrying out the policies of the Association. Under the present system, components of the Association primarily serve the policy-making and implementing function of the Board and its Executive Committee.

Assembly Agenda Committee. In the proposed system, the AAC would serve to facilitate the functioning of meetings of the Assembly. It would not have any of the powers of the Assembly in the interim between meetings of the Assembly and would probably meet the day before the first plenary session at any meeting of the Assembly to rank in order of importance the action and information items referred to the Assembly. The *Operations Manual* of the Association would specify the procedures to be followed by the AAC.

Constitutional committees. In the proposed system, the constitutional committees (Ethics, Membership, Nominating, Constitution and By-Laws, Budget, Tellers, and Reference) would report to the Executive Board, which would assume responsibility for referring matters requiring policy decision to the Assembly. The Assembly would have no need for separate committees of its own. In the present system, the constitutional committees report to the Board of Trustees for action on their recommendations. Some constitutional committees have had liaison and joint meetings with their Assembly counterparts (such as the Membership Committee), so that a broader consensus is reached before recommendations are sent to the Board of Trustees. There has occasionally, however, been duplication of effort in their work and the work of the Assembly committees.

Councils and Their Components

In the proposed system, the council chairpersons (and perhaps chairpersons of other components such as commissions) would be members of the Reference Committee, where the recommendations of components administratively housed within each council would be brought for recommended action or referral. The Reference Committee would report its recommendations for action to the Executive Board, which would have the responsibility for taking action or for referring the matter to the Assembly for policy clarification. If an interim action is taken, it would be presented for ratification by the Assembly. The responsibility for formulating position statements of the Association would rest with the Assembly. In the present system, council chairpersons also serve on the Reference Committee and present the recommendations of their subordinate components for action or referral; the Reference Committee reports to the Board of Trustees for action on their recommendations. The Assembly must be consulted and its approval obtained only if the Board of Trustees is establishing a position statement for the Association.

Reference Committee. In the present governance system, there is increased reporting to the Reference Committee by components that interact or overlap with the components within the council structure. The proposed system provides for additional members of the Reference Committee to be specified in the *Operations Manual* of the Association.

Commissions, Boards, and other special components outside the council structure. In the proposed system, these components would report to the Executive Board, which would have responsibility for interim action and reporting to the Assembly. There would be no need for joint commissions with dual representation. In the present system, there are joint commissions that report to both the Board and Assembly. All others report to the Board for action, although informational reports and requests to comment on their recommendations are often made to the Assembly for discussion by its components.

Area councils. Both the present and the proposed governance systems provide for geographic areas. The present *Procedural Code* of the Assembly defines the purpose, composition, and rules of operation of area councils. The *Operations Manual* of the Association would spell these out in the new system.

In the proposed system, the area councils would report to the Assembly through the area representative and to the Executive Board through the Vice-President from their respective areas. Area representatives would have a vote in the Assembly and area Vice-Presidents would have a vote both on the Executive Board and in the area council. The Assembly alone would make the position statements of the Association. In the present system, the area councils report only to

the Assembly and its Executive Committee; area representatives vote in the Assembly and Assembly Executive Committee; area Trustees have a vote only on the Board of Trustees and its Executive Committee.

District branches. In the proposed system, district branches "shall be established, continued, or dissolved according to the *Operations Manual* of the Association." In the present system, district branches "shall be established, continued, or dissolved according to the *Procedural Code* of the Assembly."

RATIONALE FOR DEVELOPING THE PROPOSED SYSTEM

In the original planning for the Key Conference and in the deliberations during the conference, a number of objectives were identified. Many of these, subsumed under the general heading of improvements in governance, have occupied most of the attention of the JCC during the past two years. Initially some of these, such as democratization and efficiency, seemed to be conflicting or even had mutually exclusive objectives. It became apparent that much could be accomplished by rearranging the sequence of some operations and organizing components into a unified system with elimination of the present bipartite, fragmented, and at times oppositional system. The JCC sought ways to accomplish unification of the system with minimal disturbance of the operations of the Association and with minimal, if any, increase in cost.

The following are some of the more significant objectives for improving the governmental process: 1) development of a cohesive governmental structure allowing for orderly process that could be more easily understood by the members and be more accessible to them; 2) improvement in the democratic process—giving the individual members an opportunity for greater voice and influence in the direction of the Association; 3) provision for more effective accountability of the members of the governing bodies, particularly those ultimately responsible for the direction of the Association; 4) development of an effective means for establishing priorities among the many concerns and activities of the Association; 5) improvement in efficiency, with particular reference to cost effectiveness; and 6) provision for timely and effective action by the Association, including a mechanism for emergency action.

The JCC recognizes that major improvements have been made in the democratic process in the Assembly through the requirements for 1) election by mail ballot; 2) petition nomination; 3) mandatory reporting to constituents; 4) increased representation for minorities; and 5) the possibility for recall election of Representatives and Deputy Representatives.

In addition, the JCC suggests the following improvements: 1) more proportionate representation in very large district branches by providing additional representatives with no increase in voting strength (such representation would be based on a numerical factor, for example, a Representative and Deputy Representative for each 500 members); and 2) automated voting procedures for voting by voting strength to make the process less time-consuming and cumbersome.

ADVANTAGES OF THE PROPOSED GOVERNANCE SYSTEM

The JCC has prepared a set of recommended changes in the Constitution reflecting these stated goals, which it believes may accomplish the following: 1) a unified governance system, with all subordinate components reporting to one policy-making body, the Assembly; 2) an orderly policy process, with accountability and responsibility clearly identified; 3) a small, efficient executive body (Executive Board), composed of popularly elected officers derived independently from the Assembly election system, which would handle the affairs of the Association in the interim between meetings of the Assembly and would be required to have its actions ratified by the Assembly; and 4) the assignment of ultimate responsibility for priority and policy decisions to the Assembly, a broadly based body with representatives who are close to their constituents and who are accountable to them through a recall process.

SUMMARY

The JCC has prepared recommendations for change in the governance system of the Association that would transfer policy-making responsibility to the Assembly. These have been translated into constitutional amendments by the Committee on Constitution and By-Laws and were presented to the membership at the 1978 annual meeting so that they can be voted on in 1979. These constitutional amendments will be presented for vote en bloc, since it would not be possible to implement portions of them.

The JCC neither recommends nor opposes this change in governance but endorses this model should the membership wish to achieve the transfer of policy-making responsibility to the Assembly. The JCC hopes that the Association will continue to evolve and change in response to need. To aid in the process, the JCC strongly recommends that a committee or commission be established with responsibility for assessing the operations of the Association and making recommendations for change in the future.

The JCC further emphatically recommends the establishment of a long-range planning committee for our Association. Long-range planning is a way to determine both our long-term objectives and our priorities in achieving them. It can provide us with a sense of direction, helping us to focus our energies and resources on those areas which have the most long-term significance, and at the same time provide us with a perspective that will allow us to make active, not reactive, decisions in the context of the total situation.

BRUCE ALSPACH, M.D.

Am J Psychiatry 135:10, October 1978

1977 Annual Report of the American Board of Psychiatry and Neurology, Inc.

OFFICERS AND MEMBERS OF THE BOARD

At its business meeting on October 16, 1977, the Board elected the following officers: Dr. Chester M. Pierce, President; Dr. Robert J. Joynt, Vice-President; Dr. Richard M. Steinhilber, Secretary; Dr. Melvin D. Yahr, Treasurer; and Dr. James N. Sussex, Executive Committee Member at Large.

Dr. Leonard Berg was elected to succeed Dr. Thomas W. Farmer, who had completed his second term of four years in December 1977. Drs. Marc Hollender, Richard Steinhilber, and Robert Joynt were elected to serve second terms of four years.

The 1978 Directors of the American Board of Psychiatry and Neurology, Inc., are as follows:

Nominated by the American Medical Association: Dr. Robert J. Joynt* (term expires December 1980), Dr. Richard M. Steinhilber* (term expires December 1981), Dr. Thomas R. Johns (term expires December 1978), Dr. James N. Sussex (term expires December 1978), and Dr. S. Mouchly Small (term expires December 1979).

Nominated by the American Neurological Association: Dr. Leonard Berg (term expires December 1981), Dr. Melvin D. Yahr (term expires December 1978), Dr. Patrick F. Bray (term expires December 1979), and Dr. John R. Calverley (term expires December 1980).

Nominated by the American Psychiatric Association: Dr. Marc H. Hollender* (term expires December 1981), Dr. Chester M. Pierce* (term expires December 1978), Dr. Alfred M. Freedman (term expires December 1978), Dr. Donald G. Langsley (term expires December 1979), and Dr. Richard I. Shader (term expires December 1980).

Nominated by the American Academy of Neurology: Dr. Audrey S. Penn (term expires December 1978) and Dr. Dewey K. Ziegler (term expires December 1978).

EXAMINATIONS

Part I

At the Part I (written) examination on April 11, 1977, 1,469 psychiatrists were tested; 1,215 (82.7%) passed, 254 (17.3%) failed. A total of 391 neurologists were examined; 312 (79.9%) passed, 79 (20.1%) failed.

For the 1978 Part I examination, 2,091 psychiatrists and 543 neurologists have accepted assignment. (See table 1 for the number of candidates declared eligible and notified for Part I in 1977 and table 2 for a comparison of these figures with other years).

TABLE 1
Number Declared Eligible and Notified for Part I Written Examination April 11, 1977

Item	Psychiatry	Neurology	Total
Number declared eligible and notified	1,995	424	2,419
Number who declined or withdrew	325	7	332
Number remaining for written examination as of March 1977	1,670	417	2,087

TABLE 2
Five-Year Comparison of Number Declared Eligible and Notified for Part I Examination

Item	1973	1974	1975	1976	1977
Total eligible	1,999	2,098	3,146	3,113	2,419
Total who accepted examination	1,381	1,821	2,408	2,391	2,087
Total who actually appeared	1,205	1,627	2,240	2,191	1,860

Part II

There were 333 candidates—258 psychiatrists and 75 neurologists—present at the Part II examination given in Seattle, Wash., February 7–8, 1977 (see table 3). A total of 617 candidates—474 psychiatrists and 143 neurologists—were tested in Washington, D.C., April 18–19, 1977 (see table 4). A total of 444 candidates—353 psychiatrists and 91 neurologists—were tested in Kansas City, Mo., June 6–7, 1977 (see table 5). One of the Board's largest Part II examinations to date was held in Philadelphia, Pa., October 16–17, 1977. A total of 1,095 candidates were tested—942 psychiatrists and 153 neurologists (see table 6).

Future examination sites for 1978 include Los Angeles, Calif. (April 17–18), Cincinnati, Ohio (June 5–6), and Boston, Mass. (November 6–7).

CHILD PSYCHIATRY

Members of the 1978 Committee on Certification in Child Psychiatry are Dr. Richard S. Ward, chairperson, Dr. Jeanne Spurlock, vice-chairperson, Dr. Joseph Green, secretary, Dr. Norman Bernstein, Dr. Norbert Enzer, Dr. Irving Philips, and Dr. Michael I. Cohen, liaison from the American Board of Pediatrics.

At its March 14–15, 1977, examinations in Chicago, the committee examined a total of 136 candidates. A total of 96 candidates (70.6%) passed. Of the remaining 40 candidates, 26 (19.1%) conditioned the examination, and 14 (10.3%) failed.

This is an edited version of the report of the American Board of Psychiatry and Neurology, Inc., to the American Psychiatric Association in Washington, D.C., April 1, 1978.

*These Directors are serving their second term of four years and are not eligible for reappointment.

The committee's 1978 examination was held February 27–28, 1978, in New Orleans for approximately 170 candidates. The committee continued to offer its "retake option" in the 1978 examination. As in 1977, this option was made available to reexaminees as well as those candidates taking the examination for the first time. Under this option, candidates who feel they have performed badly in an oral section have the opportunity to repeat one oral section during the examination. This option does not apply to the committee's written examination.

The committee agreed at its September 1977 business meeting that a pass on the child psychiatry written examination would be valid for a period of seven years beginning with the February 1978 examination.

The committee also decided to experiment with allowing those candidates who fail only the written examination to retake that examination in their own geographic region. The proctor for such an examination would have to be a known, reliable child psychiatrist in a center near the candidate's residence but not at the candidate's own institution. Such

an examination would be given on the same day as the oral examinations for all other child psychiatrists.

Under the leadership of Dr. Irving Philips, the committee is currently engaged in a project designed to involve child psychiatry training directors in the certification process. In the proposed model for the project, one aspect involves utilization of a questionnaire that asks the training director to grade the trainee as to how the training director feels the trainee will perform on the child psychiatry certification examination. Training directors would also be asked to grade the trainee's performance during the training program. Plans call for gathering data that could be transmitted to child psychiatry training directors pointing out similarities or differences between the training director's ratings and the actual performance. This would also give the committee some basic data on how reliable the training directors are in evaluating residents.•

BOARD DECISIONS AND ITEMS OF INTEREST

The following major policy decisions were enacted by the Board in 1977:

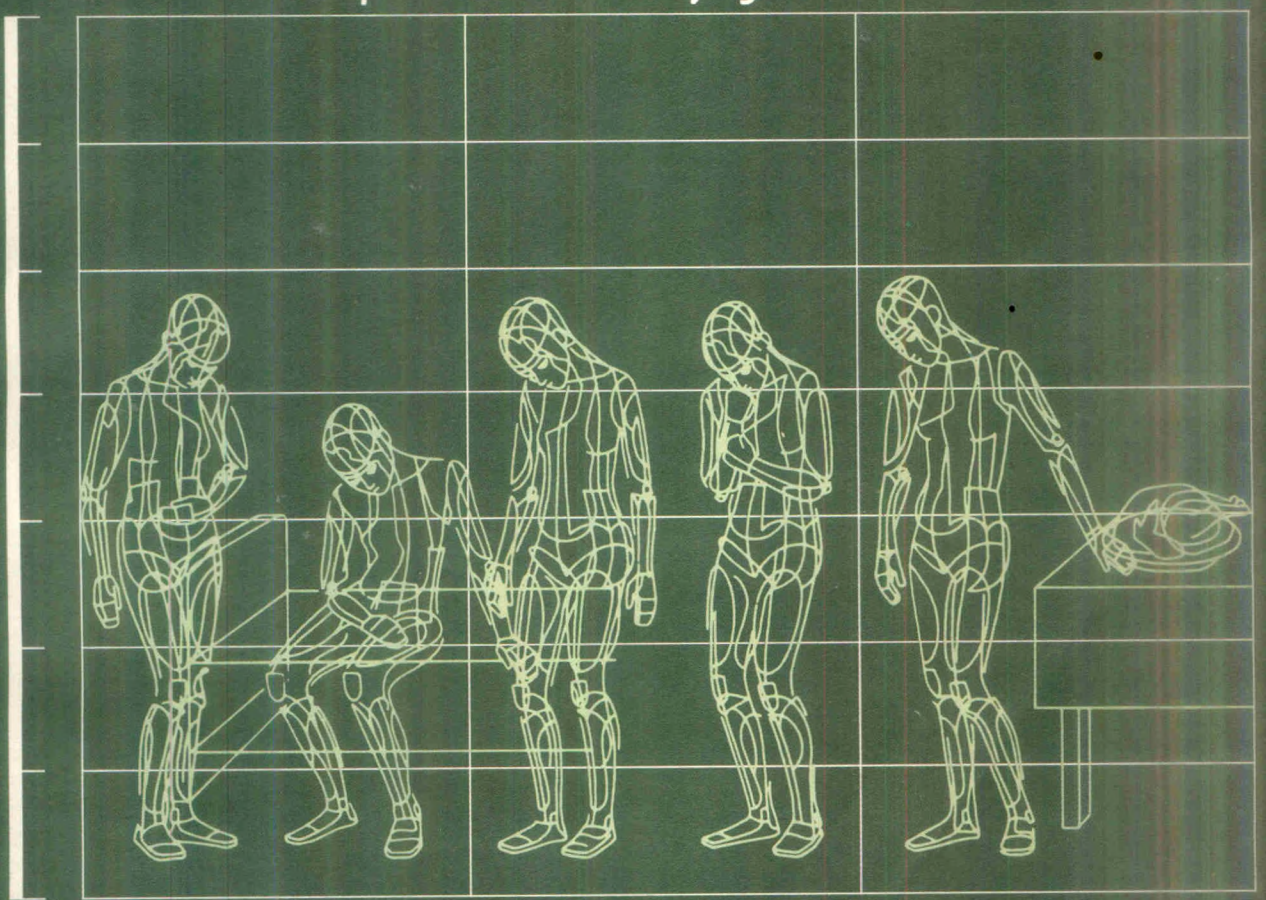
1. Effective November 1, 1977, the following criteria for admission to examination are applicable to those applicants with foreign training qualifications: the candidate must have had full-time specialty training in a manner equivalent in length of time and content to that required for U.S. training; the candidate must successfully complete a certification examination in the country of training in the specialty in which the physician is seeking admission to examination; the candidate must possess an unlimited license to practice medicine in a state or commonwealth of the United States or a province of Canada; and the candidate must have achieved certification within the past seven years, and if certification was achieved more than 7 years ago, then the candidate must have had one year of clinical practice in a setting in which his/her professional work has been observed by at least two ABPN diplomates in that specialty and documented by two letters of sponsorship from such diplomates.

2. Effective November 1, 1977, for those candidates who have completed the first postgraduate year of training in a training center located outside the United States or Canada the following criteria will be acceptable for admission to examination: the candidate must have completed a full year of supervised postgraduate training equivalent to that required by the Board for United States and Canadian graduates as evidenced by appropriate documentation. (This documentation should consist of a letter of verification from the institution at which the training was taken and from the person who was in charge of the training.) The burden for verification for this year rests with the candidate.

3. Beginning at the October 1977 Part II examination, the previously administered one hour of oral examination in Neurology for Psychiatry candidates will be replaced by a written examination. The written examination is based on a series of audiovisual vignettes of neurologic patients. Each vignette will last for approximately three to four minutes and will be followed by written multiple-choice examination questions pertinent to the brief patient presentation.

4. The Board approved the use of an audiovisual examination in child neurology to substitute for one hour of live patient examination in child neurology for candidates for Certification in Neurology with Special Competence in Child Neurology. The substitution went into effect at the Board's October 1977 Part II examination.

5. The Board agreed to accept the proposal of the Credentials Committee that three years of training in general psychiatry could include a pattern of two years in general psychiatry and one year in child psychiatry provided that two years of this training is spent in a single approved program.



6. The Board agreed that as of January 1, 1978, the per diem for Part II examiners be raised from $50 to $65.

At its November 1977 policy meeting the Board took the following significant actions: 1) reaffirmed its position against a primary Board of Emergency Medicine; 2) agreed to establish a task force to initiate an audiovisual written examination in psychiatry for neurologists; 3) agreed to confer the title "Member of Test Committee of ABPN" on consultant members of ABPN examinations committees and to issue a certificate as a form of recognition to those consultants who have served on the Part I Examination Committee and on the Neurology for Psychiatrists Audiovisual Written Examination Committee; 4) agreed that the grading system for the Part II examination be revised beginning with the November 1978 examination. The new grading system to be used would be high pass, pass, conditional, and fail; 5) decided to include a release form on the Part I application, which would ask the candidates to authorize release of examination results to training programs; 6) authorized the Executive Committee and Executive Director to seek out a research associate; 7) agreed to distribute the following policy statement to appropriate individuals. "Individuals who contribute questions, videotapes, or other subject material for ABPN examinations are reminded that they must avoid explicit discussion of that material in seminars, review courses, or other instructional procedures used by candidates to prepare themselves for the examination, lest the principles of conflict of interest and unfair advantage to some candidates be applicable"; 8) assumed sponsorship of a proposal suggested by Dr. Donald Langsley in conjunction with the Board's Research and Development Committee. The proposal would compare evaluation of residents by training directors during the training period with subsequent performance on Board examinations; and 9) agreed to draw up a statement regarding an ethical code for ABPN Directors.

LESTER H. RUDY, M.D.
Executive Director

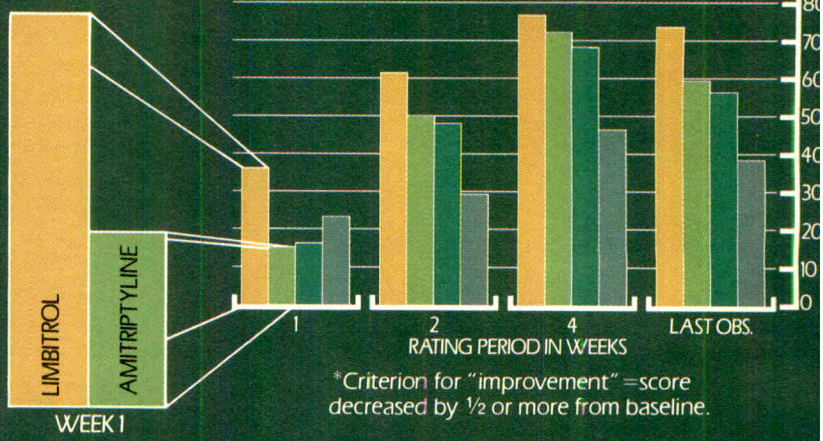
Within one week
A better response
For twice as many patients

compared to amitriptyline alone

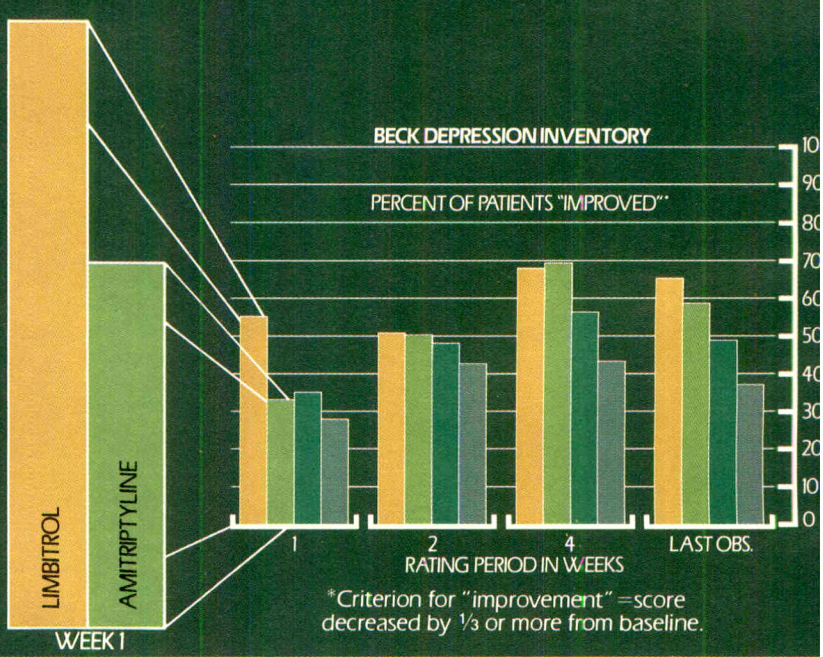
Limbitrol®

For rapid relief of symptoms
in moderate to severe
depression and anxiety

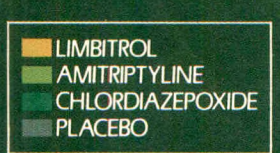
ROCHE



Please see last page of this advertisement for summary of product information.



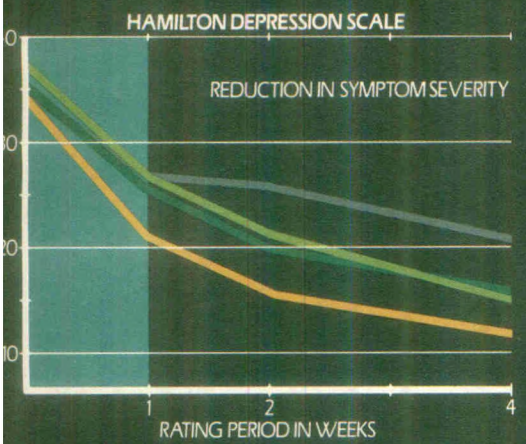
Within one week Twice as many patients improved–soone

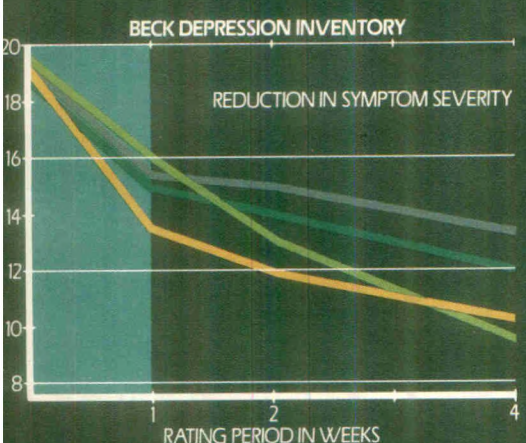


In a rigidly controlled nationwide multicenter study

The rating scales agree

- ☐ Patients respond faster
  - ☐ Limbitrol—in the first week approximately 2/3 of those who improved had already done so
  - ☐ Amitriptyline—only about 1/3 of those who eventually responded had done so by week one
- ☐ High correlation among all major indices employed including Physician's and Patient's Global Evaluations





ROCHE

Please see last page of this advertisement for summary of product information.

nd better than with amitriptyline alone

Reduction in severity of symptoms based on mean observed value at each rating period.

Reduction in severity of symptoms based on mean observed value at each rating period.

The symptoms subside

Hamilton Depression Scale Items

- ☐ insomnia
- ☐ psychic anxiety
- ☐ somatic anxiety
- ☐ agitation
- ☐ suicidal ideation
- ☐ worthlessness

Beck Depression Inventory Items

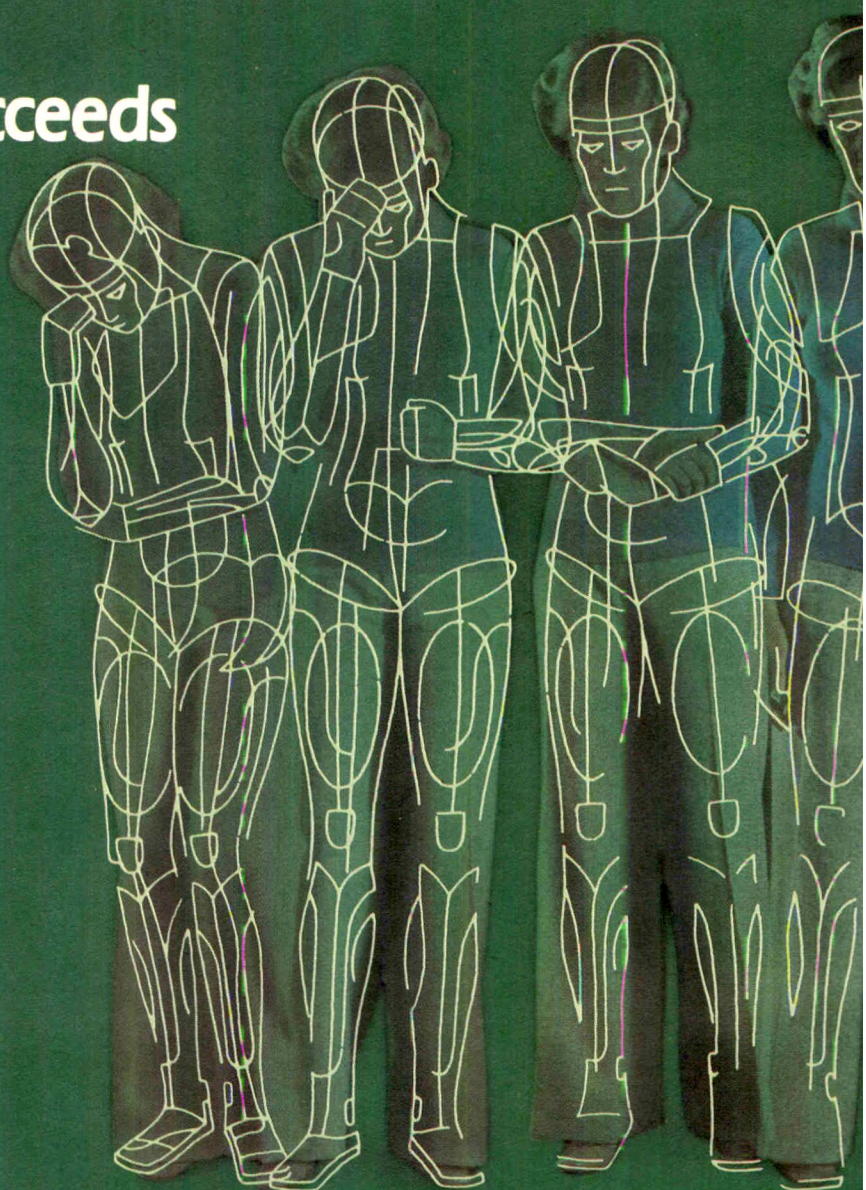
- ☐ pessimism
- ☐ dissatisfaction
- ☐ guilt
- ☐ social withdrawal
- ☐ anorexia

By week one, Limbitrol patients' symptoms had, on average, improved to a point not reached by amitriptyline patients until week two.

The data presented are based on a rigidly controlled nationwide multicenter study of 279 patients with a diagnosis of primary depression with symptoms of depression and anxiety of moderate to severe degree.

Provides the well established antidepressant effect of amitriptyline with the proven antianxiety effect of Librium® (chlordiazepoxide HCl)

Limbitrol®



For rapid relief of moderate to severe depression and anxiety

A change for the better comes sooner–within one week

In a rigidly controlled nationwide multicenter study

The therapy succeeds

- ☐ Better patient compliance
- ☐ Lower dropout rate
  - ☐ Despite a higher incidence of drowsiness, the dropout rate due to side effects was lower with Limbitrol than with amitriptyline alone (Limbitrol 4%, amitriptyline 13%, chlordiazepoxide 1%)
  - ☐ The dropout rate due to therapeutic failure was lower with Limbitrol (Limbitrol 2%, amitriptyline 6%, chlordiazepoxide 12%)

ROCHE

Please see last page of this advertisement for summary of product information.

How to initiate and maintain therapy

Select dosage strength appropriate for each patient

☐ Limbitrol 10-25 is recommended for most patients

☐ Limbitrol 5-12.5 may be indicated for those who do not tolerate higher doses and for elderly patients

Specify daily dosage based on symptom severity

☐ An initial dosage of three tablets is recommended

☐ Dosage may be increased to six tablets or decreased to two tablets daily as necessary

☐ Once a satisfactory response is obtained, evaluate response, and, if necessary, reduce dosage to smallest amount needed to maintain remission

Utilize dosage options to best accommodate individual patient needs

☐ T.I.D. or Q.I.D., familiar regimens most suited for patients who tolerate medication without undue drowsiness

☐ Two tablets one hour before bedtime and one tablet midday may minimize daytime drowsiness and help relieve a common target symptom—insomnia

☐ Entire dosage *h.s.* to take maximum advantage of the sedative effect

Tablets 10-25 each containing 10 mg chlordiazepoxide and 25 mg amitriptyline (as the hydrochloride salt)

Tablets 5-12.5 each containing 5 mg chlordiazepoxide and 12.5 mg amitriptyline (as the hydrochloride salt)

Limbitrol®

For rapid relief of moderate to severe depression and anxiety

Your guide to patient management

1. Discuss with patients the probability that they will experience drowsiness, especially during the first week.
2. Reassure your patients that drowsiness is one indication that the medication is working and that it may help alleviate their insomnia.
3. Encourage patients to report if drowsiness becomes troublesome so that, if necessary, dosage schedule can be adjusted or the symptom treated.
4. Caution patients about the combined effects with alcohol or other CNS depressants. Let them know that the additive effects may produce a harmful level of sedation and CNS depression.
5. Caution patients about activities requiring complete mental alertness, such as operating machinery or driving a car.
6. Warn pregnant patients and patients of childbearing age that the safety of Limbitrol in pregnancy has not yet been established.

Please see complete product disclosure for other pertinent information.

Limbitrol should not be used under the following circumstances:

1. Hypersensitivity to benzodiazepines or tricyclic antidepressants.
2. Should not be given with an MAO inhibitor. To replace an MAO inhibitor with Limbitrol, discontinue MAO inhibitor for a minimum of 14 days before cautiously initiating Limbitrol therapy.
3. During the acute recovery phase following myocardial infarction.

Limbitrol®

For rapid relief of moderate depression and anxiety

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of moderate to severe depression associated with moderate to severe anxiety.

Contraindications: Known hypersensitivity to benzodiazepines or tricyclic antidepressants. Do not use with monoamine oxidase (MAO) inhibitors or within 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Contraindicated during acute recovery phase following myocardial infarction.

Warnings: Use with great care in patients with history of urinary retention or angle-closure glaucoma. Severe constipation may occur in patients taking tricyclic antidepressants and anticholinergic-type drugs. Closely supervise cardiovascular patients. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, especially high doses. Myocardial infarction and stroke reported with use of this class of drugs.)

***Usage in Pregnancy:* Use of minor tranquilizers during the first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Since physical and psychological dependence to chlordiazepoxide have been reported rarely, use caution in administering Limbitrol to addiction-prone individuals or those who might increase dosage; withdrawal symptoms following discontinuation of either component alone have been reported (nausea, headache and malaise for amitriptyline; symptoms [including convulsions] similar to those of barbiturate withdrawal for chlordiazepoxide).

Precautions: Use with caution in patients with a history of seizures, in hyperthyroid patients or those on thyroid medication, and in patients with impaired renal or hepatic function. Because of the possibility of suicide in depressed patients, do not permit easy access to large quantities in these patients. Caution patients about possible combined effects with alcohol and other CNS depressants and against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Periodic liver function tests and blood counts are recommended during prolonged treatment. Amitriptyline component may block action of guanethidine or similar antihypertensives. Concomitant use with other psychotropic drugs has not been evaluated: sedative effects may be additive. Discontinue several days before surgery. Limit concomitant administration of ECT to essential treatment. See Warnings for precautions about pregnancy. Limbitrol should not be taken during the nursing period. Not recommended in children under 12. In the elderly and debilitated, limit to smallest effective dosage to preclude ataxia, oversedation, confusion or anticholinergic effects.

Adverse Reactions: Most frequently reported are those associated with either component alone: drowsiness, dry mouth, constipation, blurred vision, dizziness and bloating. Less frequently occurring reactions include vivid dreams, impotence, tremor, confusion and nasal congestion. Many depressive symptoms including anorexia, fatigue, weakness, restlessness and lethargy have been reported as side effects of both Limbitrol and amitriptyline. Granulocytopenia, jaundice and hepatic dysfunction have been observed rarely.

This list includes adverse reactions not reported with Limbitrol but requiring consideration because they have been reported with one or both components or closely related drugs:

Cardiovascular: Hypotension, hypertension, tachycardia, palpitations, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Euphoria, apprehension, poor concentration, delusions, hallucinations, hypomania and increased or decreased libido.

Neurologic: Incoordination, ataxia, numbness, tingling and paresthesias of the extremities, extrapyramidal symptoms, syncope, changes in EEG patterns.

Anticholinergics: Disturbance of accommodation, paralytic ileus, urinary retention, dilatation of urinary tract.

Allergic: Skin rash, urticaria, photosensitization, edema of face and tongue, pruritus.

Hematologic: Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia.

Gastrointestinal: Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, black tongue.

Endocrine: Testicular swelling and gynecomastia in the male, breast enlargement, galactorrhea and minor menstrual irregularities in the female and elevation and lowering of blood sugar levels.

Other: Headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, jaundice, alopecia, parotid swelling.

Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. I.V. administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestation and treatment.

Dosage: Individualize according to symptom severity and patient response. Reduce to smallest effective dosage when satisfactory response is obtained. Larger portion of daily dose may be taken at bedtime. Single *h.s.* dose may suffice for some patients. Lower dosages are recommended for the elderly.

Limbitrol 10-25, initial dosage of three to four tablets daily in divided doses, increased up to six tablets or decreased to two tablets daily as required. Limbitrol 5-12.5, initial dosage of three to four tablets daily in divided doses, for patients who do not tolerate higher doses.

Supplied: Limbitrol 10-25 tablets each containing 10 mg chlordiazepoxide and 25 mg amitriptyline (as the hydrochloride salt) and Limbitrol 5-12.5 tablets each containing 5 mg chlordiazepoxide and 12.5 mg amitriptyline (as the hydrochloride salt)—bottles of 100 and 500; Tel-E-Dose® packages of 100; Prescription Paks of 50.

The American Psychiatric Association announces publication of two volumes reporting the Conference on Education of Psychiatrists

held at Lake of the Ozarks, Missouri, June 9-15, 1975. Organized by the A.P.A. in cooperation with the American Academy of Child Psychiatry, the American Association of Chairmen of Departments of Psychiatry, and the American Association of Directors of Psychiatric Residency Training.

1. PSYCHIATRIC EDUCATION: PROLOGUE TO THE 1980's, Library Bound, 544 pages, $15.00.

This is a substantive, highly readable, report of the Conference, written by Anne H. Rosenfeld with an Editorial Board comprising: Ewald W. Busse, M.D., Chairperson of the Conference, Walter E. Barton, M.D., Bernard Holland, M.D., Donna Norris, M.D., Melvin Sabshin, M.D., Jeanne Spurlock, M.D., and Robert L. Robinson, M.A. (Staff Consultant).

The volume contains ten chapters covering the topical structure of the Conference: Goals and Values; Competence, Evaluation, and Quality Control; The Resident; Faculty; Educational Methods: Means in the Service of Ends; The Program Environment; Research; The Economics of Residency Training; Psychiatry in Its Social Context; and Retrospect and Prospect. It also contains nine appendices describing the organization of the Conference and its participants, together with selected model programs and related informational materials of value.

2. THE WORKING PAPERS OF THE 1975 CONFERENCE ON EDUCATION OF PSYCHIATRISTS Paper bound, 432 pages, $12.50.

Sixty two leading psychiatric educators served on seven preparatory commissions, one for each of seven topic areas, and prepared advance working papers as a basis for Conference deliberations. The topics and Commission Chairpersons were: Social Issues and Needs (James N. Sussex, M.D.); Goals and Objectives (Morton F. Reiser, M.D.); The Resident (David R. Hawkins, M.D.); Content, Methodology, Faculty and Environment (Milton Greenblatt, M.D.); Research (Daniel X. Freedman, M.D.); Economics (Herzl Spiro, M.D.); Evaluation and Quality Control (Eric Pfeiffer, M.D.). The Chairpersons, together with the Conference Chairperson, served as the Editorial Board for this volume.

Papers commenting on the reports of the commissions, published here for the first time, were presented at the Conference by Melvin Sabshin, M.D., Eugene B. Brody, M.D., Jeanne Spurlock, M.D., Jack R. Ewalt, M.D., Robert J. Stoller, M.D., James R. Comer, M.D., and Bernard Holland, M.D.

Must the MBD child take a controlled drug in school?

Not if he's taking Cylert® (pemoline) C IV

Children can be cruel. Their teasing about taking noontime medication can cause serious problems for the child with MBD.

Here's how Cylert eliminates this problem:

- Once a day dosage at home
- Eliminates mid-day school dose

In addition, Cylert offers these benefits:

- Avoids ups and downs of drug action brought about by multiple daily dosage
- Control of medication by the parent
- A chewable dosage form
- Less physician paper work (Cylert is in schedule IV)
- Safety and efficacy proven in extensive clinical studies*

*Copy of the Cylert Monograph available to Physicians on written request.

When not to use medication

Cylert should not be used for (and will not be effective in) simple cases of overactivity in school-age children.

Neither should it be used in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

The physician should rely on a complete history of the child and a thorough description of symptoms from both parents and teacher before postulating a diagnosis of MBD.

ABBOTT

Please see next page for Prescribing Information.

Cylert and Cylert Chewable Tablets

(pemoline)

Prescribing Information

Indications: *MINIMAL BRAIN DYSFUNCTION IN CHILDREN*—as adjunctive therapy to other remedial measures (psychological, educational, social).

Special Diagnostic Considerations: The cause of minimal brain dysfunction (MBD) is unknown. Diagnosis of MBD involves the use of medical, psychological, educational, and social tools, since no single diagnostic test is adequate.

MBD is characterized by chronic moderate to severe hyperactivity, short attention span, distractibility, emotional lability, and impulsivity. Nonlocalizing (soft) neurological signs, learning disability, and abnormal EEG may or may not be present. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. In the primary therapy of MBD, appropriate educational placement is essential and psychosocial intervention is generally necessary. When these measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

Contraindications: Cylert (pemoline) is contraindicated in patients with known hypersensitivity or idiosyncrasy to the drug. (See ADVERSE REACTIONS.)

Warnings: Cylert is not recommended for children less than 6 years of age since its safety and efficacy in this age group have not been established.

Sufficient data on the safety and the efficacy of the long-term use of Cylert in children with minimal brain dysfunction are not yet available.

A temporary suppression of the predicted growth rate (weight and/or height gain) has been reported for children receiving long-term stimulant therapy. A definite causal relationship between stimulant drugs and this finding has not been established.

Precautions: Liver function tests should be performed periodically during therapy with Cylert. The drug should be discontinued if abnormalities are revealed and confirmed by follow-up tests. (See ADVERSE REACTIONS regarding reports of abnormal liver function tests and jaundice.)

Cylert should be administered with caution to patients with significantly impaired hepatic or renal function.

The interaction of Cylert with other drugs has not been studied in humans. Patients who are receiving Cylert concurrently with other drugs, especially drugs with CNS activity, should be monitored carefully.

Cylert failed to demonstrate a potential for self-administration in primates. However, the pharmacologic similarity of pemoline to other psychostimulants with known dependence liability suggests that psychological and/or physical dependence might also occur with Cylert. There have been isolated reports of transient psychotic symptoms occurring in adults following the long-term misuse of excessive oral doses of pemoline. Cylert should be given with caution to emotionally unstable patients who may increase the dosage on their own initiative.

Usage during Pregnancy and Lactation: The safety of Cylert (pemoline) for use during pregnancy and lactation has not been established.

Fertility, reproduction, and teratology studies were conducted in laboratory animals. Pemoline, in doses of 18.75 or 37.5 mg./kg./day, had no effect on the fertility of male or female rats. The drug, when given to pregnant rats (from gestation day 15 through weaning) and to rabbits (from gestation days 6-18) at these same dosage levels, produced no teratogenic or embryotoxic effects, and had no effect on the viability of the young at birth. However, increased incidences of stillbirths and cannibalization were observed when pemoline was given to rats at these dosage levels, beginning 14 days prior to conception.

Adverse Reactions: Insomnia is the most frequently reported side effect of Cylert; it usually occurs early in therapy, prior to an optimum therapeutic response. In the majority of cases it is transient in nature or responds to a reduction in dosage.

Anorexia with weight loss may occur during the first weeks of therapy. In the majority of cases it is transient in nature; weight gain usually resumes within three to six months.

Stomach ache, skin rashes, increased irritability, mild depression, nausea, dizziness, headache, drowsiness, and hallucinations have been reported.

Elevations of SGOT, SGPT, and serum LDH have occurred in patients taking Cylert, usually after several months of therapy. These effects appear to be reversible upon withdrawal of the drug, and are thought to be manifestations of a delayed hypersensitivity reaction. There have also been a few reports of jaundice occurring in patients taking Cylert; a causal relationship between the drug and this clinical finding has not been established.

There have been reports of dyskinetic movements of the lips, face, and extremities occurring with the use of Cylert. Convulsive seizures have also been reported. A definite causal relationship between Cylert and these reactions has not been established.

Mild adverse reactions appearing early during the course of treatment with Cylert often remit with continuing therapy. If adverse reactions are of a significant or protracted nature, dosage should be reduced or the drug discontinued.

How Supplied: Cylert (pemoline) is supplied as monogrammed, grooved tablets in three dosage strengths:

18.75 mg. tablets (white) in bottles of 100 (**NDC** 0074-6025-13)
37.5 mg. tablets (orange-colored) in bottles of 100 (**NDC** 0074-6057-13)
75 mg. tablets (tan-colored) in bottles of 100 (**NDC** 0074-6073-13)

Cylert Chewable is supplied as monogrammed, grooved tablets in one dosage strength:

37.5 mg. tablets (orange-colored)
in bottles of 100 (**NDC** 0074-6088-13)

A Psychiatric Glossary

Edited by a subcommittee of the AMERICAN PSYCHIATRIC ASSOCIATION Committee on Public Information.

The new Fourth Edition marks a striking expansion of definitions: 400 terms have been added and many of the terms appearing in earlier editions have received revised explanations. In addition to the GLOSSARY's continuing value to lawyers, teachers, journalists, social workers, and others, the new edition will be useful to medical students and first year residents in psychiatry.

Some major changes in the Fourth Edition:

- Expansion from 102 to 156 pages to accommodate 400 new terms
- New tables of terms in seven areas of contemporary concern
  - Drugs Used in Psychiatry
  - Legal Terms
  - Neurologic Deficits
  - Psychological Tests
  - Research Terms
  - Schools of Psychiatry
  - Sleep Disorders
- A comprehensive set of terms used in behavior therapy is included for the first time.

Paperback edition—$3.00 each, (See coupon for bulk discounts), may be ordered from the AMERICAN PSYCHIATRIC ASSOCIATION, Publications Sales, 1700 18th St. N.W., Washington, D.C. 20009.

Hardback edition—$7.95 may be ordered from Basic Books, Inc., 10 East 53rd Street, New York, New York 10022.

MANUAL OF PSYCHIATRIC PEER REVIEW

by the Peer Review Committee of the American Psychiatric Association, Donald G. Langsley, M.D., Chairperson in cooperation with the Joint Task Force on Diagnostic Criteria for Analyzability of the American Psychoanalytic Association, William Offenkrantz, M.D., Chairperson, and the Peer Review Committee of the American Academy of Child Psychiatry. Larry B. Silver, M.D., Chairperson.

"This Manual provides a set of guidelines for district branches of APA and their peer review committees which should be adapted and modified in terms of local criteria, standards, and practices. The guidelines are not intended to be hard and fast rules. They are screening criteria, and not regulations to control practice. They are so designed that they can be utilized by non-physicians to identify those cases that can profitably be reviewed by psychiatrists serving on peer review committees. This document should be viewed as transitional, subject to revision as experience is gained, and continually updated in response to advances in psychiatric knowledge and changes in patterns of practice. . . . The application of these standards, and refinement through experience must rest with the peer review committees of district branches. . . . It should help them to move ahead in the development of a peer review for American psychiatry."

Robert W. Gibson, M.D.
President

Part I titled PSYCHIATRIC PEER REVIEW contains sections on Basic Relationships and Responsibilities, Appointment of Peer Review Committees, Funding, Operations and Procedures, Medical Care Evaluation Studies, Appeals Processes, Special Problems, Confidentiality, Educational Aspects, Medical Ethics, Advocacy, Interdisciplinary Aspects, with Appendices on Model Screening Format for Inpatient Treatment for Alcoholism, Model Screening Format for Outpatient Treatment, Sample Form for Requesting Extension of Office Treatment, Claims Review Guidelines Suggestions, APA Position Papers on Peer Review, Bibliography.

Part II titled PSYCHOANALYTIC PEER REVIEW has sections on Steps in Peer Review for Psychoanalysis, Guidelines for Model Criteria Sets, Pilot Application of Guidelines for Model Criteria Sets, Sample Peer Review Form, Sample data from Pilot Applications of Guidelines, and Glossary of Terms Used.

Part III titled PEER REVIEW AND CHILD PSYCHIATRY contains sections of Special Considerations, Legal Rights of Children, Issue of Confidentiality, Conclusions, References, and Appendices on Model Screen Criteria Format for Intermediate Care, for Acute Care in a Short Stay Facilities, and for Partial Hospitalization, Outpatient Diagnostic Evaluation Procedures, and Outpatient Treatment for Children and Adolescents.

Artist Leonard Leff uses sculpture to express the painful depression he once experienced. He remembers it as "a lowering of the flame of life. My energies ebbed, my will to live decreased, and I found myself retreating from the activities of life to a more introverted existence."

WHEN DEPRESSION EXPRESSES ITSELF

SINEQUAN®
(DOXEPIN HCl)

ANTIDEPRESSANT EFFECTIVENESS with convenient once-a-day *h.s.* dosage*

NEW 150-MG CAPSULE†

Also available in:
100-mg, 75-mg, 50-mg, 25-mg, 10-mg CAPSULES and ORAL CONCENTRATE, 10 mg/ml, in 120-ml (4-oz) bottles

*The total daily dosage of Sinequan, up to 150 mg, may be administered on a once-a-day schedule without loss of effectiveness.

† The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

See Brief Summary on next page for information on contraindications, warnings, precautions and adverse reactions.

ANTIDEPRESSANT EFFECTIVENESS

SINEQUAN®
(DOXEPIN HCl)
NEW 150-MG CAPSULE*

*The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

CONVENIENT ONCE-A-DAY *h.s.* DOSAGE

which may improve patient compliance. The total daily dosage, up to 150 mg per day, may be given on a once-a-day schedule without loss of effectiveness. Sinequan may also be given on a divided dosage schedule, up to 300 mg per day.

PROMINENT SEDATIVE EFFECT

which may help to relieve the difficulty in falling and staying asleep, and the early-morning awakening often associated with depression.

ESTABLISHED ANTIANXIETY ACTIVITY

to help alleviate the anxiety which often accompanies clinical depression.

USUALLY WELL TOLERATED

At doses up to 150 mg per day, Sinequan does not generally affect the antihypertensive activity of guanethidine and related compounds. Tachycardia and hypotension have been reported occasionally. Drowsiness is the most commonly observed side effect. Dry mouth, blurred vision, constipation and urinary retention have been reported.

EXTENDED RANGE OF DOSAGE STRENGTHS

for flexibility in individualizing therapy.

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. These disorders should be ruled out, particularly in older patients. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.

Warnings. The once-a-day dosage regimen of SINEQUAN (doxepin HCl) in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.

Usage with Alcohol: It should be borne in mind that alcohol ingestion may increase the danger inherent in any intentional or unintentional SINEQUAN overdosage. This is especially important in patients who may use alcohol excessively.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy. Prescriptions should be written for the smallest feasible amount.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.

Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, numbness, paresthesias, ataxia, and extrapyramidal symptoms and seizures.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, edema, photosensitization, and pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, anorexia, and aphthous stomatitis have been reported. (See anticholinergic effects.)

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice, alopecia, and headache have been occasionally observed as adverse effects.

Dosage and Administration. For most patients with illness of mild to moderate severity, starting daily dose of 75 mg is recommended. Dosage may subsequently be increased decreased at appropriate intervals and according to individual response. The usual optimu dose range is 75 mg/day to 150 mg/day.

In more severely ill patients higher doses may be required with subsequent gradual increase 300 mg/day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding dose of 300 mg/day.

In patients with very mild symptomatology or emotional symptoms accompanying organ disease, lower doses may suffice. Some of these patients have been controlled on doses as lo as 25-50 mg/day.

The total daily dosage of SINEQUAN (doxepin HCl) may be given on a divided or once-a-d dosage schedule. If the once-a-day schedule is employed the maximum recommended dose 150 mg/day. This dose may be given at bedtime. **The 150 mg capsule strength is intended f maintenance therapy only and is not recommended for initiation of treatment.**

Antianxiety effect is apparent before the antidepressant effect. Optimal antidepressant effe may not be evident for two to three weeks.

Overdosage.

A. Signs and Symptoms

1. Mild: Drowsiness, stupor, blurred vision, excessive dryness of mouth.
2. Severe: Respiratory depression, hypotension, coma, convulsions, cardiac arrhythmias ar tachycardias.

Also: urinary retention (bladder atony), decreased gastrointestinal motility (paralytic ileus hyperthermia (or hypothermia), hypertension, dilated pupils, hyperactive reflexes.

B. Management and Treatment

1. Mild: Observation and supportive therapy is all that is usually necessary.
2. Severe: Medical management of severe SINEQUAN overdosage consists of aggressi supportive therapy. If the patient is conscious, gastric lavage, with appropriate precautions prevent pulmonary aspiration, should be performed even though SINEQUAN is rapidly absorbe The use of activated charcoal has been recommended, as has been continuous gastric lavag with saline for 24 hours or more. An adequate airway should be established in comatose patien and assisted ventilation used if necessary. EKG monitoring may be required for several day since relapse after apparent recovery has been reported. Arrhythmias should be treated with th appropriate antiarrhythmic agent. It has been reported that many of the cardiovascular and CN symptoms of tricyclic antidepressant poisoning in adults may be reversed by the slow intr venous administration of 1 mg to 3 mg of physostigmine salicylate. Because physostigmine rapidly metabolized, the dosage should be repeated as required. Convulsions may respond standard anticonvulsant therapy; however, barbiturates may potentiate any respiratory depre sion. Dialysis and forced diuresis generally are not of value in the management of overdosag due to high tissue and protein binding of SINEQUAN.

Supply. SINEQUAN is available as capsules containing doxepin HCl equivalent to: 10 mg, 75 m and 100 mg doxepin: bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). 25 mg ar 50 mg doxepin: bottles of 100, 1000, 5000, and unit-dose packages of 100 (10 x 10's). 150 m doxepin: bottles of 50, 500, and unit-dose packages of 100 (10 x 10's). SINEQUAN Or Concentrate (10 mg/ml) is available in 120 ml bottles with an accompanying dropper calibrate at 5 mg, 10 mg, 15 mg, 20 mg, and 25 mg. Each ml contains doxepin HCl equivalent to 10 m doxepin. Just prior to administration, SINEQUAN Oral Concentrate should be diluted wit approximately 120 ml of water, whole or skimmed milk, or orange, grapefruit, tomato, prune pineapple juice. SINEQUAN Oral Concentrate is not physically compatible with a number carbonated beverages. For those patients requiring antidepressant therapy who are o methadone maintenance, SINEQUAN Oral Concentrate and methadone syrup can be mixe together with Gatorade®, lemonade, orange juice, sugar water, Tang®, or water; but not wit grape juice. Preparation and storage of bulk dilutions is not recommended.

More detailed professional information available on request.

PFIZER INC.

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

Emotional withdrawal, suspiciousness and delusions managed
Harold B. is now asymptomatic with no hepatic, renal, ocular or phototoxicity.*

LOXITANE® Loxapine Succinate

Permits rapid management of Harold's suspiciousness and behavioral symptoms

Shy, retiring son forced to join family business after college. Became increasingly immobilized, sitting at desk and staring into space. Occasionally overheard muttering about the "powers killing me." Taken to psychiatrist's office, he was given LOXITANE® Loxapine Succinate capsules 50 mg initially. Scheduled for daily sessions and LOXITANE 20 mg t.i.d. Diagnosis: Acute schizophrenia.

Permits aggressive titration for rapid establishment of optimal symptom management

Short-term treatment goals focussed on symptom control. Within four days, dosage titrated up from 20 mg to 50 mg t.i.d. By the fifth day, Harold was able to visit psychiatrist alone. Delusions and conceptual disorganization began to subside.

Permits sustained symptom management with minimal risk of phototoxicity and other serious adverse effects

During third week, became aware of parental conflict. He began to explore his true career interest as a naturalist. Experienced no phototoxicity despite long hours out-of-doors. LOXITANE reduced to 30 mg t.i.d., with symptom management maintained.

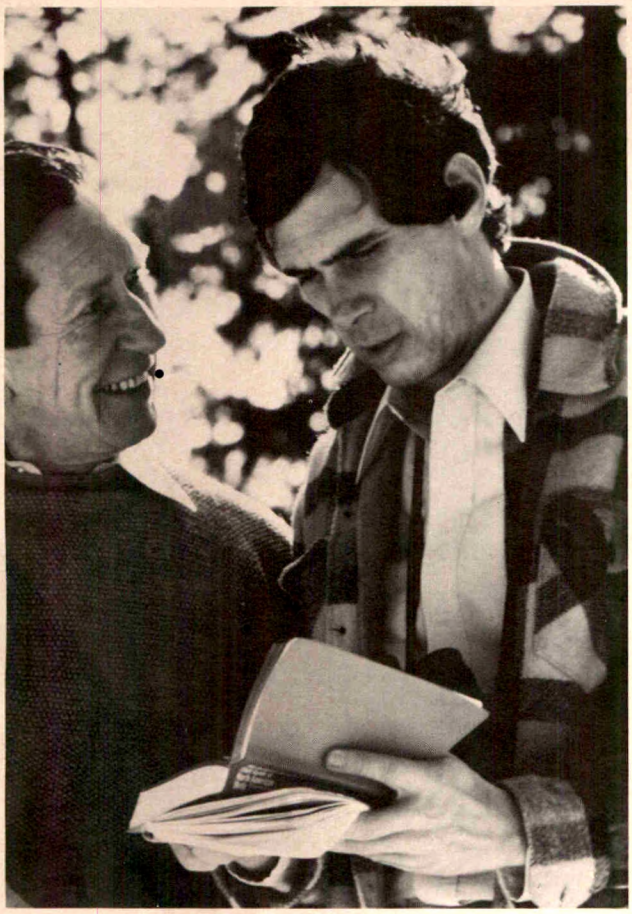
Side effects are usually mild, transitory and easily managed

Consistence in schizophrenic symptom management and tolerance promotes patient compliance

Now, after six months on LOXITANE 20 mg t.i.d. and regular therapeutic sessions, Harold continues his outdoor interests, but has agreed to return part-time to his father's business on a trial basis. He remains under control and free from occurrence of side effects. Much less emotionally withdrawn, but lacks spontaneity.

*Transient liver enzyme changes not definitely related to LOXITANE have been reported. Although not reported to date, possibility of hepatic, renal, ocular, or phototoxicity cannot be ruled out at this time. Not an actual patient, but a simulation to illustrate the action of LOXITANE as reported in clinical studies.

See LOXITANE prescribing information on the following page for indications, warnings and precautions and for more detailed information concerning side effects.



Loxitane®
LOXAPINE SUCCINATE

Lederle

Capsules: 5 mg, 10 mg, 25 mg, 50 mg

Maximum management... minimum risk

Maximum management... minimum risk

Loxitane®
LOXAPINE SUCCINATE
Lederle

Recommended Daily Dosage

Initial Dosage	MILD 10 mg b.i.d.	MODERATE 10 mg t.i.d or q.i.d.	SEVERE 25 mg b.i.d.
First 7 to 10 days	Increase dosage until psychotic symptoms are controlled. Dosage should not exceed 250 mg/day. Usual dosage during titration: 50 to 150 mg/day.		
Maintenance Dosage	Adjust to lowest effective level. Usual maintenance dosage: 60 to 100 mg/day. Many patients are controlled with dosages as low as 20 to 60 mg/day.		

Brief Summary
LOXITANE® Loxapine Succinate Capsules
LOXITANE® C Loxapine Hydrochloride Oral Concentrate
INDICATIONS: Manifestations of schizophrenia.
CONTRAINDICATIONS: Comatose or severely depressed states; hypersensitivity to the drug.
WARNINGS: Safe use during pregnancy or lactation has not been established; weigh potential benefits to possible hazards. Not recommended for use in children under 16. May impair mental and/or physical abilities especially during early therapy; warn ambulatory patients about activities requiring alertness and concomitant use of alcohol or other CNS depressants. Not recommended for management of behavioral complications in mentally retarded patients.
PRECAUTIONS: Use with extreme caution in patients with a history of convulsive disorders; use with caution in patients with cardiovascular disease or in those with glaucoma or a tendency to urinary retention particularly when on concomitant anticholinergic medication. Loxapine has an antiemetic effect in animals which might occur in man masking signs of overdosage of toxic drugs and obscuring intestinal obstruction or brain tumor. Since possible ocular toxicity cannot be excluded, observe carefully for pigmentary retinopathy and lenticular pigmentation.
ADVERSE REACTIONS: CNS effects, other than extrapyramidal, infrequent. Mild drowsiness may occur at beginning of therapy or upon dosage increase, usually subsides with continued therapy. Sedation, dizziness, faintness, staggering gait, muscle twitching, weakness and confusional states have been reported. Extrapyramidal reactions often occur early in treatment manifested by Parkinson-like symptoms (tremor, rigidity, excessive salivation, masked facies, akathisia) controllable by dosage reduction or antiparkinson drugs at usual dosages. Dystonic and dyskinetic reactions, while less frequently occurring, may be more severe, requiring dosage reduction or temporary withdrawal plus appropriate counteractive drugs. Persistent Tardive Dyskinesia may appear during prolonged therapy or following discontinuance, the risk greater in the elderly, especially females, on high dosage. Symptoms, persistent and in some patients apparently irreversible, are characterized by rhythmical involuntary movement of the tongue, face, mouth and jaw sometimes accompanied by involuntary movement of extremities. Since there is no known effective treatment, discontinue all antipsychotic drugs if symptoms appear. Reinstitution of treatment, increased dosage, or switching to another agent may mask syndrome. The syndrome may not develop if medication is stopped when fine vermicular movements of the tongue first appear. Cardiovascular Effects: Tachycardia, hypotension, hypertension, lightheadedness and syncope. ECG changes, not known to be related to loxapine use, have been reported. Skin: Dermatitis, edema of face, pruritus, seborrhea. Possible photosensitivity and/or phototoxicity; skin rashes of unknown etiology seen in a few patients in hot summer months. Anticholinergic: Dry mouth, nasal congestion, constipation, blurred vision (more likely to occur with concomitant use of antiparkinson agents). Other: Nausea, vomiting, weight gain or loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, polydipsia. Rarely, galactorrhea and menstrual irregularity of unknown etiology.

Just Published . . .

The Rape Victim

by Elaine Hilberman, M.D.

Mythologies about rape are legion. However, in recent years behavioral scientists have accumulated a body of information about rape and about an unfolding series of reactions experienced by the victim after rape. The aim of this concise, tightly reasoned book is to summarize what is now known about the needs and experiences of the victim and her family, and to provide a framework in which the clinician can more knowledgeably supply assistance and support. This document, published by the American Psychiatric Association, is the result of a project of the Association's Committee on Women.

Pointing out that the profound impact of rape stress is best understood in the context of rape as "a crime against the person and not the hymen," Dr. Hilberman sees rape as the ultimate violation of the self short of homicide, as an act of violence and humiliation in which not only is the victim's very existence threatened, and her inner and most private space invaded, but her autonomy and control are totally demolished. Dr. Hilberman shows that if and when the victim reports the crime, she is confronted with a complex series of yet additional stresses growing out of her contact with the hospital, police, courts, media and community opinion. Additionally, her crisis differs from other crises in that her usual social support system is likely to be disrupted. Her immediate needs are for empathy and safety, and a sense of control over what is happening in her dealings with the several agencies. Dr. Hilberman shows that in the absence of sensitivity to these needs, the experience of reporting becomes another assault.

This book presents a professional, sobering, and balanced picture of the problems of the rape victim and details what the clinician must know—about local hospital policy, criminal justice procedure, rape statutes, and community attitudes and services—in order to be able to treat victims with an understanding of the larger context in which rape occurs.

ELAINE HILBERMAN, M.D., *is in the Department of Psychiatry at the University of North Carolina School of Medicine.*

"Please don't cry."

His mother's depressed. Her sleepless nights are filled with anxieties. She's become irritable and "unloving." He doesn't understand why she has changed.

In anxious depressed patients, Goldberg and Finnerty* found "...patients treated with imipramine pamoate tended ($P<.09$) to have a better quality of sleep than those treated with amitriptyline."

The overall results of the study indicate that both imipramine pamoate and amitriptyline were equally effective in treating neurotic depression.

Before prescribing Tofranil-PM, please review a summary of the full prescribing information on the following page.

Tofranil-PM®

imipramine pamoate

Unsurpassed among tricyclics in treating symptoms of anxious depression

*Goldberg H L, Finnerty R J: Which tricyclic for depressed outpatients, imipramine pamoate or amitriptyline? Dis Nerv Syst 38: 785-789 (Oct.) 1977.

Geigy

Tofranil-PM®
imipramine **pamoate**

Geigy

As anxiety, agitation, sleep disturbances, and other depressive symptoms are relieved, mood and motivation may be markedly improved.

Patients are usually alert and capable of functioning at more normal levels of behavior.

Tofranil-PM encourages patient compliance because one capsule lasts from bedtime to bedtime.

Good results are usually seen at the starting dose of one 75-mg capsule h.s.

For many patients, dosage can be safely increased to 150 mg daily.

As with all tricyclics, sedation may occur. Please caution patients against driving or operating dangerous machinery.

Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg of imipramine hydrochloride.

Tofranil-PM®
brand of imipramine pamoate

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil-PM, brand of imipramine pamoate, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;
—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;
—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;
—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;
—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as operating an automobile or machinery, the patient should be cautioned accordingly.

Usage in Children: Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil-PM, brand of imipramine pamoate, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil-PM, brand of imipramine pamoate, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic. Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: In adult outpatients, therapy should be initiated on a once-a-day basis with 75 mg./day. This may be increased to 150 mg./day which is the dose level which usually obtains optimum response. If necessary, dosage may be increased to 200 mg./day. Dosage should be modified as necessary by clinical response and any evidence of intolerance. Daily dosage may be given at bedtime, or in some patients in divided daily doses.

Hospitalized patients should be started on a once-a-day basis with 100-150 mg./day and may be increased to 200 mg./day. Dosage should be increased to 250-300 mg./day if there is no response after two weeks.

Following remission, maintenance medication may be required for a longer period of time at the lowest dose that will maintain remission. The usual adult maintenance dosage is 75-150 mg./day on a once-a-day basis, preferably at bedtime.

In adolescent and geriatric patients, capsules of Tofranil-PM, brand of imipramine pamoate, may be used when total daily dosage is established at 75 mg. or higher. It is generally unnecessary to exceed 100 mg./day in these patients. This dosage may be given once a day at bedtime or, if needed, in divided daily doses.

How Supplied: Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.)

Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Association

This book reports six studies that add to the growing body of data demonstrating the feasibility of covering mental illness under health insurance. Although in some ways it may be considered a supplement to APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (Reed, Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal employees, documenting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health benefit plans.
- Coverage of mental illness under collective bargaining agreements of selected unions.
- Utilization of care for mental conditions under the Canadian health insurance program, which gives the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

80pp. Paperbound

Haldol®
(haloperidol)
tablets/concentrate/injection

Promptly controls psychotic symptoms... usually leaving the patient more responsive to therapy

Rapid onset of therapeutic effect in a wide range of psychotic symptoms.[1-4]

Helps avoid long-term hospitalization.[1-3,5]

Minimal risk of hypotension, oversedation, or troublesome anticholinergic effects.[1,4,6,7,9-11]
Transient hypotension occurs rarely; severe orthostatic hypotension has not been reported. Although some instances of drowsiness have been reported, marked sedation is rare.

Permits aggressive titration to effective dosage levels for optimal control.[5,6]

Often leaves patient with improved insight,
with a renewed interest in the environment, and more likely to participate in therapeutic efforts.[1,7]

Common side effects easily controlled.[1,4-6,8,9]
Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

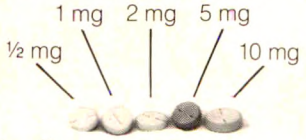
*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Please turn page for summary of prescribing information.

concentrate

A tasteless, odorless, colorless liquid concentrate for better patient compliance: 2 mg per ml.



injection

A rapid-acting injection for psychiatric emergencies: 5 mg per ml,* with 1.8 mg methylparaben and 0.2 mg propylparaben per ml, and lactic acid for pH adjustment to 3.4 ± 0.2.

tablets

5 tablet strengths for convenience in individualizing dosage:

HALDOL® (haloperidol)

tablets/concentrate/injection

A dosage form for every therapeutic need

Summary of Prescribing Information

Contraindications: Severe depression, coma, CNS depression due to centrally-acting depressants, Parkinson's disease, hypersensitivity to the drug.

Warnings: ***Usage in Pregnancy:*** Safe use in pregnancy or in women likely to become pregnant has not been established; use only if benefit clearly justifies potential hazards. Infants should not be nursed during drug treatment.

Usage in Children: Safety and effectiveness not established; not recommended in pediatric age group.

Combined Use With Lithium: Patients receiving lithium plus haloperidol should be monitored closely for early evidence of neurological toxicity.

General: Bronchopneumonia, sometimes fatal, has followed use of major tranquilizers, including haloperidol. Prompt remedial therapy should be instituted if dehydration, hemoconcentration or reduced pulmonary ventilation occurs, especially in the elderly. Decreased serum cholesterol and/or cutaneous and ocular changes have been reported with chemically-related drugs, although not with haloperidol. Mental and/or physical abilities required for hazardous tasks or driving may be impaired. Alcohol should be avoided due to possible additive effects and hypotension.

Precautions: Administer cautiously to patients: (1) with severe cardiovascular disorders, due to the possibility of transient hypotension and/or precipitation of anginal pain (if a vasopressor is required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur); (2) receiving anticonvulsant medication since HALDOL haloperidol may lower the convulsive threshold; (3) with known allergies or a history of allergic reactions to drugs; (4) receiving anticoagulants. Concomitant antiparkinson medication, if required, may have to be continued after HALDOL haloperidol is discontinued because of different excretion rates; if both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson drugs, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used for mania in cyclic disorders, there may be a rapid mood swing to depression. Severe neurotoxicity may occur in patients with thyrotoxicosis receiving antipsychotic medication, including HALDOL haloperidol.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions:* Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which were usually mild to moderately severe and usually reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally, extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Antiparkinson drugs may be required. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases.

Withdrawal Emergent Neurological Signs: Abrupt discontinuation of short-term antipsychotic therapy is generally uneventful. However, some patients on maintenance treatment experience transient dyskinetic signs after abrupt withdrawal. In certain cases these are indistinguishable from "Persistent Tardive Dyskinesia" except for duration. It is unknown whether gradual withdrawal will reduce the occurrence of these signs, but until further evidence is available haloperidol should be gradually withdrawn.

Persistent Tardive Dyskinesia: Although rarely reported with HALDOL haloperidol, tardive dyskinesia may appear during or after long-term therapy. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and sometimes appear irreversible; there is no known effective treatment and all antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent.

Other CNS Effects: Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms.

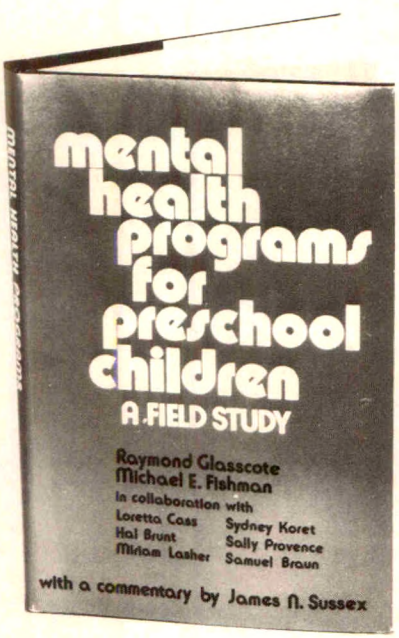
Cardiovascular Effects: Tachycardia and hypotension. ***Hematologic Effects:*** Reports of mild, usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis; agranulocytosis rarely reported and only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice reported. ***Dermatologic Reactions:*** Maculopapular and acneiform reactions, isolated cases of photosensitivity, loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

The injectable form is intended only for acutely agitated psychotic patients with moderately severe to very severe symptoms.

Caution: Federal law prohibits dispensing without prescription.

Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

HALDOL tablets are manufactured by McNeil Laboratories Co., Dorado, Puerto Rico 00646.



* haloperidol present as the lactate

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.
President, American Association of Psychiatric Services for Children

Patients become easier to manage

...with a low incidence of adverse side effects on

MOBAN®
molindone HCl

- an effective antipsychotic agent
- not a phenothiazine

FAVORABLE BENEFIT/RISK PROFILE, WHICH MAY ENHANCE COMPLIANCE*

NO incidence	Tolerance development Hepatotoxic changes Ophthalmological changes Excessive weight gain Impotence Decreased libido Skin pigmentation Thyroid function changes Persistent tardive dyskinesia
LOW incidence	Sedation Adverse drug interactions Hypotension Hematological changes Lactation Amenorrhea Autonomic changes Skin rash Nonpersistent symptoms of tardive dyskinesia
MODERATE incidence	Extrapyramidal reactions

*This table compiled from clinical and field reports, according to the best available information.

Further advantages with MOBAN®

The pharmacological effect from a single oral dose persists for 24-36 hours, permitting *h.s.* dosage, once the daily dosage level is established.

Several clinicians have reported that obese patients on MOBAN® frequently experienced a marked reduction in weight toward normal weight.

How to use MOBAN®

The usual starting dose is 50-75 mg/day. You can increase to 100 mg/day in 3-4 days. Titrate individually up or down depending on patient response. Some chronic, treatment-resistant patients may require an increase to 400 mg/day. (However, the long-term safety of 400 mg/day has not been established.) Please refer to complete prescribing information for further dosage instructions.

For complete prescribing information, please see next page.

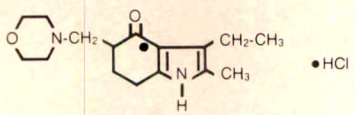
DUPONT



Patients become easier to manage on

MOBAN®
molindone HCl

5 mg	10 mg	25 mg
Endo	Endo	Endo

DESCRIPTION MOBAN® (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN® is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN® (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN® antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN® exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN® (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN® being excreted in urine and feces.

INDICATIONS MOBAN® (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN® (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in the pregnant patient have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose— 20 mg/kg/day—10 days
no adverse effect
40 mg/kg/day—10 days
no adverse effect

Pregnant Mice oral dose— 20 mg/kg/day—10 days
slight increase resorptions
40 mg/kg/day—10 days
slight increase resorptions

Pregnant Rabbits oral dose— 5 mg/kg/day—12 days
no adverse effect
10 mg/kg/day—12 days
no adverse effect
20 mg/kg/day—12 days
no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN® (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN® (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS Some patients receiving MOBAN® (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN® Caution should be exercised where increased activity may be harmful.

MOBAN® does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN® has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological

Extrapyramidal Reactions

Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia

Motor restlessness may occur early.

Parkinson Syndrome

Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome

Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System

Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological

There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN® may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects

Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with MOBAN® therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN®.

Cardiovascular

Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological

Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN® (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN®.

Skin

Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN® usage alone.

MOBAN® (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN® is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia

Although rarely reported with MOBAN® (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN® (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50-75 mg/day.

—Increase to 100 mg/day in 3 or 4 days.

—Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.

—An increase to 225 mg/day may be required in patients with severe symptomatology.

—Some chronic, treatment resistant patients, may require up to 400 mg/day (however, the long term safety of 400 mg/day has not been established).

Elderly and debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild—5 mg-15 mg three or four times a day.
2. Moderate—10 mg-25 mg three or four times a day.
3. Severe—225 mg/day may be required.

Dosages may be administered once a day.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN® (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN® is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN® (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN® (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidot must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by MOBAN® in animals this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN® from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN® is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized MOBAN® in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles of 100 and 1000 with potencie and colors as follows: 5 mg orange, 10 mg lavender, 25 mg light green.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

Computerized transaxial tomography (CT scan) is an important new noninvasive technique that can help in determining the etiology of epileptic seizures. Shown here is a single slice from a color-enhanced CT scan of the brain of a patient with epilepsy. The absence of vascula

A proven way to start seizure control

MYSOLINE®
(primidone) Tablets 50 mg, 250 mg Suspension 250 mg/5 ml

A single entity with multiple anticonvulsant properties

Primidone itself has anticonvulsant activity. In addition, its major metabolite, phenylethylmalonamide (PEMA), exerts an anticonvulsant effect of its own and also enhances the anticonvulsant action of the second metabolite, phenobarbital. In patients refractory to phenytoin and phenobarbital, primidone may prove effective as the sole therapy.[1]

Multiple indications—grand mal, psychomotor, and focal epileptic seizures

In grand mal, MYSOLINE is comparable in efficacy to phenytoin and phenobarbital.[2,3] In psychomotor seizures, phenobarbital is rarely effective.[1] In focal seizures, phenytoin used alone is not indicated[4]—and, according to Forster,[3] MYSOLINE is markedly more effective than phenobarbital, which should dispel the misconception that MYSOLINE is "just a phenobarbital." (See chart below.)

Efficacy ratings* of anticonvulsants in epilepsy

Agent	Grand Mal	Psychomotor	Focal
Mysoline	++++	++++	++++
Hydantoinates (phenytoin)	++++	+++	+++
Barbiturates (phenobarbital)	++	++	++

*Relative effectiveness, ++++ being most effective. Adapted from Forster, F. M.[3]

Consider it first for major motor epilepsies

MYSOLINE® (primidone) Ayerst®

See next page for Brief Summary and references.

Start seizure control with MYSOLINE® (primidone)

Initial dose in children over 8 years of age and adults: 250 mg daily at bedtime

BRIEF SUMMARY
(For full prescribing information, see package circular.)
MYSOLINE®
Brand of **PRIMIDONE** *Anticonvulsant*

ACTIONS: MYSOLINE raises electro- or chemoshock seizure thresholds or alters seizure patterns in experimental animals. The mechanism(s) of primidone's antiepileptic action is not known.

Primidone *per se* has anticonvulsant activity as do its two metabolites, phenobarbital and phenylethylmalonamide (PEMA). In addition to its anticonvulsant activity, PEMA potentiates that of phenobarbital in experimental animals.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several weeks before it can be assessed.

Usage in pregnancy: The effects of MYSOLINE in human pregnancy and nursing infants are unknown.

Recent reports suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Data are more extensive with respect to diphenylhydantoin and phenobarbital, but these are also the most commonly prescribed anticonvulsants; less systematic or anecdotal reports suggest a possible similar association with the use of all known anticonvulsant drugs.

The reports suggesting an elevated incidence of birth defects in children of drug-treated epileptic women cannot be regarded as adequate to prove a definite cause and effect relationship. There are intrinsic methodologic problems in obtaining adequate data on drug teratogenicity in humans; the possibility also exists that other factors, *e.g.*, genetic factors or the epileptic condition itself, may be more important than drug therapy in leading to birth defects. The great majority of mothers on anticonvulsant medication deliver normal infants. It is important to note that anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that the removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus.

The prescribing physician will wish to weigh these considerations in treating or counseling epileptic women of childbearing potential.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

PRECAUTIONS: The total daily dosage should not exceed 2 g. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 g per day. The initial dose is 250 mg. Increments of 250 mg are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 g. A typical dosage schedule for the introduction of MYSOLINE is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg daily at bedtime	*2nd Week* 250 mg b.i.d.
3rd Week 250 mg t.i.d.	*4th Week* 250 mg q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg, with gradual weekly increases of 125 mg a day, to a daily total usually between 500 mg and 750 mg.

In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances: for initiation of combination therapy; during "transfer" therapy; for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.).

HOW SUPPLIED: MYSOLINE Tablets—No. 430—Each tablet contains 250 mg of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg of primidone (scored), in bottles of 100 and 500.
MYSOLINE Suspension—No. 3850—Each 5 ml (teaspoonful) contains 250 mg of primidone, in bottles of 8 fluidounces.

For depressed patients who must function effectively in daily activities...

PAMELOR®
(nortriptyline HCl) NF
25mg. Capsules

Patients remain alert.

Most depressed patients must function effectively in their daily activities, on the job or at home. For these patients, PAMELOR capsules may be an appropriate therapeutic choice. PAMELOR relieves depression, yet rarely causes daytime drowsiness. As with all antidepressants, however, patients should be cautioned against driving or operating hazardous machinery.

Insomnia of depression begins to improve within a week.

PAMELOR capsules are effective for relieving insomnia, a cardinal symptom of depressive illness. Patients begin to sleep better within the first week of therapy. The full therapeutic effect of PAMELOR is usually observed by the second week.

PAMELOR therapy is well tolerated.

In 90 studies, a total of 818 patients were treated with PAMELOR capsules. Of the patients who improved completely or markedly, over half (54%) had no side effects. Those who experienced side effects most commonly complained of dry mouth.

For Brief Summary please see last page of this advertisement.

SANDOZ
PHARMACEUTICALS
EAST HANOVER, N.J. 07936

PAMELOR®
(nortriptyline HCl) NF
25 mg. Capsules

The antidepressant for the patient who must remain alert and active.

- relieves depression without causing problem daytime drowsiness
- insomnia of depression begins to improve within a week
- PAMELOR therapy is well tolerated

Indications: For relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Hypersensitivity. Should not be given concomitantly with MAO inhibitors or within 2 weeks of the use of this drug since hyperpyretic crises, severe convulsions, and fatalities have occurred when similar tricyclic antidepressants were used in such combinations. Cross-sensitivity with other dibenzazepines is a possibility. Contraindicated during acute recovery period after myocardial infarction.

Warnings: Use with caution in patients with cardiovascular disease because of tendency to produce sinus tachycardia and prolong conduction time. Myocardial infarction, arrhythmia, and strokes have occurred. May block antihypertensive action of guanethidine and similar agents. Because of anticholinergic activity, use cautiously in patients with glaucoma or a history of urinary retention. Patients with a history of seizures should be followed closely because the drug is known to lower the convulsive threshold. Great care is required for hyperthyroid patients and those taking thyroid medication because of possible development of cardiac arrhythmia. Caution patients about possibility of impaired mental and/or physical ability to operate a motor vehicle or dangerous machinery. Response to alcoholic beverages may be exaggerated and may lead to suicidal attempts. Safe use during pregnancy, lactation, and women of childbearing potential has not been established and the drug should not be given unless clinical situation warrants potential risk. Not recommended for use in children.

Precautions: Psychotic symptoms may be exacerbated in schizophrenic patients. Increased anxiety and agitation may occur in overactive or agitated patients. Manic-depressive patients may experience shift to manic phase. Hostility may be aroused. Concomitant administration of reserpine may produce a "stimulating" effect. Watch for possible epileptiform seizures during treatment. Use cautiously with anticholinergic or sympathomimetic drugs. Concurrent electroconvulsive therapy may increase hazards associated with nortriptyline HCl. When possible, discontinue drug several days prior to surgery. Potentially suicidal patients require supervision and protective measures during therapy. Prescriptions should be limited to the least possible quantity. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: The pharmacologic similarities among the tricyclic antidepressant drugs require that each of the following reactions be considered when nortriptyline is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia, panic, nightmares; hypomania; exacerbation of psychosis.

Neurologic: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alteration in EEG patterns; tinnitus.

Anticholinergic: Dry mouth and rarely, associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue), drug fever, cross-sensitivity with other tricyclic drugs.

Hematologic: Bone-marrow depression, including agranulocytosis; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black-tongue.

Endocrine: Gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness, fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though these are not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Dosage and Administration: *Usual adult dose* – 25 mg. three or four times daily; dosage should begin at a low level and increase as required. As an alternate regimen, the total daily dosage may be given once-a-day. *Elderly and Adolescent* - 30 to 50 mg. per day, in divided doses, or the total dosage may be given once-a-day. Doses above 100 mg. per day and use in children are not recommended. If a patient develops minor side effects, the dosage should be reduced. The drug should be discontinued promptly if adverse effects of a serious nature or allergic manifestations occur.

How Supplied: Capsules 10 mg. and 25 mg.; solution 10 mg./5 cc.

For more detailed information see full prescribing information.

Everybody knows somebody who's been helped.

The United Way is reaching out. It goes into every neighborhood. To every age group. Across every income level.
To help. In a thousand ways.
A neighbor. A relative. Maybe someone down the street who's out of work. Or sick. Or in trouble.
Chances are the United Way helps someone you know.
Maybe someday it'll be helping you.

Thanks to you it works...

Prescribing Information for

Lidone™ (molindone hydrochloride)

DESCRIPTION — LIDONE (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

LIDONE is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4(5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

ACTIONS — LIDONE (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, LIDONE antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, LIDONE exerts its effect on the ascending reticular activating system.

Human metabolic studies show LIDONE (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24 to 36 hours. There are 36 recognized metabolites with less than 2 to 3% unmetabolized LIDONE being excreted in urine and feces.

INDICATIONS — LIDONE (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS — LIDONE (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS

Usage in Pregnancy: Studies in pregnant patients have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats Oral Dose —
20 mg/kg/day — 10 days, no adverse effect
40 mg/kg/day — 10 days, no adverse effect

Pregnant Mice Oral Dose —
20 mg/kg/day — 10 days, slight increase resorptions
40 mg/kg/day — 10 days, slight increase resorptions

Pregnant Rabbits Oral Dose —
5 mg/kg/day — 12 days, no adverse effect
10 mg/kg/day — 12 days, no adverse effect
20 mg/kg/day — 12 days, no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of LIDONE (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of LIDONE (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS — Some patients receiving LIDONE (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving LIDONE. Caution should be exercised where increased activity may be harmful.

LIDONE does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

LIDONE has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS

CNS Effects — The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological Extrapyramidal Reactions — Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia — Motor restlessness may occur early.

Parkinson Syndrome — Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome — Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System — Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological — There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with LIDONE may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects — Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with LIDONE therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with LIDONE.

Cardiovascular — Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological — Lens opacities and pigmentary retinopathy have not been reported where patients have received LIDONE (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with LIDONE.

Skin — Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with LIDONE usage alone.

LIDONE (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when LIDONE is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia — Although rarely reported with LIDONE (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION — Initial and maintenance doses of LIDONE (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50 to 75 mg/day.
- — Increase to 100 mg/day in three or four days.
- — Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.
- — An increase to 225 mg/day may be required in patients with severe symptomatology.
- — Some chronic, treatment-resistant patients may require up to 400 mg/day; (however, the long-term safety of 400 mg/day has not been established).

Elderly or debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild — 5 mg to 15 mg three or four times a day.
2. Moderate — 10 mg to 25 mg three or four times a day.
3. Severe — 225 mg/day may be required.

Dosage may be administered once a day.

DRUG INTERACTIONS — Potentiation of drugs administered concurrently with LIDONE (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when LIDONE is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE — Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of LIDONE (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of LIDONE (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by LIDONE in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized LIDONE from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of LIDONE is excreted unmetabolized in the urine.) However, poor response of the patient may justify use of these procedures.

While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized LIDONE in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED — LIDONE (molindone hydrochloride) capsules are supplied in bottles of 100 in the following dosage strengths and colors:

5 mg (**NDC** 0074-5542-13) blue and cream
10 mg (**NDC** 0074-5543-13) red and cream
25 mg (**NDC** 0074-5544-13) brown and cream

AMERICAN PSYCHIATRIC ASSOCIATION

UNIVERSITY COLLEGE LIBRARY

BACK HOME

THORAZINE®

brand of

CHLORPROMAZINE

Tablets:
50 and 100 mg
of the HCl

Home from the hospital. He went in with a psychiatric emergency but left more like himself—delusions, hallucinations, and other psychotic target symptoms under control with 'Thorazine'. And 'Thorazine' maintenance can help keep him out of the hospital in the future.

From initial psychiatric emergency through maintenance therapy, 'Thorazine' offers effective antipsychotic therapy with 18 convenient dosage forms and strengths. This means you can precisely tailor dosage to the individual patient's needs throughout the entire course of therapy.

'Thorazine'. The most widely tested and highly flexible antipsychotic available today.

Helps return psychotic patients to reality

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: The possibility of extrapyramidal reactions from 'Thorazine' may confuse the diagnosis of Reye's syndrome or other encephalopathy. Therefore, avoid use in children or adolescents with suspected Reye's syndrome.

Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or obscure diagnosis of conditions such as intestinal obstruction, brain tumor, and Reye's syndrome (see Warnings). Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Single Unit Packages of 100 (intended for institutional use only).
Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only).
Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.
Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

CHARLES C THOMAS · PUBLISHER

• FAMILY THERAPY AND EVALUATION THROUGH ART •

By **Hanna Yaxa Kwiatkowska,** *The George Washington Univ., Washington, D. C. Foreword by* **Lyman C. Wynne.** Written by the innovator of family art therapy, this book describes the use of art therapy with families for evaluation of family dynamics, treatment and research.

The author outlines the developments in the field from its inception to the present. She covers the steps required in assessing the problems of the troubled family and in carrying out the necessary treatment. Case material is presented which demonstrates the merits of this powerful approach. Methods of research arising from the material generated by the evaluative and therapeutic procedures are also examined.

The author stresses that family art therapy is unique in that individual family members and the family as a group communicate with one another and with the therapist through their expressive art. Their pictures and sculptures embody family process and suggest the etiology of the difficulties in the family relations. That is, the transactions of the family engaged in art procedures reproduce their transactions in day-to-day life, thus offering an unbiased view of the family system and interrelationships. Their individual and joint artwork, says the author, provides revelations and changes that cannot be denied. This is the source of the effectiveness of family art therapy.

The importance of this contribution to the practice of family therapy must not be underestimated. The book will appeal to a variety of therapists and counselors who are using or considering the use of family therapy and evaluation through art. *'78, 296 pp., 125 il. (12 in color), 7 tables, $21.75*

INTRODUCING NEUROPSYCHOLOGY: The Study of Brain and Mind *by* **Stuart J. Dimond,** *Univ. College, Cardiff, Wales.* This book delves into enigmas of mental life to arrive at an expanded perception of precisely how the mind and behavior are related to the underlying machinery of the brain. The initial portion of the text outlines the status of neuropsychology among the brain sciences, the methods used in this discipline, and fundamental brain systems. The effects of brain injury and disease, the development of the brain in relation to the mind, the split-brain condition in man, and other topics are discussed in this section. Remaining chapters focus on the cerebral cortex, the infant brain, the normal brain, mechanisms and functions of the higher mental states, neurological processes in psychiatric illness, and the development of technology for control of the brain. *'78, 236 pp., 12 il., 2 tables, $13.75*

THE HAND TEST: A New Projective Test with Special Reference to the Prediction of Overt Aggressive Behavior (5th Ptg.) *by* **Barry Bricklin** *and* **Zygmunt A. Piotrowski,** *both of The Jefferson Medical College of Philadelphia, Philadelphia, Pennsylvania, and* **Edwin E. Wagner,** *Univ. of Akron, Akron, Ohio.* This text describes a practical, projective personality test designed to make it possible to predict not only potentially aggressive overt behavior but many other facets of interpersonal behavior as well. It consists of pictures of human hands in various ambiguous poses. The subject is asked to tell what each hand may be doing. A large section is devoted to use of the test in daily clinical practice — including diagnostic hints and procedures pertaining to use of the test with individual cases. *'78, 112 pp. (5 3/4 x 8 3/4), 1 il., 25 tables, $7.50*

CAREER DEVELOPMENT AND COUNSELING OF WOMEN *edited by* **L. Sunny Hansen,** *Univ. of Minnesota, Minneapolis, and* **Rita S. Rapoza,** *Wilson Learning Corp., Eden Prairie, Minnesota. (46 Contributors)* This unique text includes articles on psychological and environmental variables which inhibit or facilitate women's development and affect their decisions, not only about work, but also about their life roles with respect to family, leisure, and community. The text also provides information which will help teachers, counselors, psychologists and others to find ways to help women expand their career and life-style options. Specific topics include occupational socialization, negotiating and planning for multiple roles, assessment of women's career interests, and cross-cultural perspectives of female career development. An extensive bibliography supplements the text. *'78, 672 pp., 57 tables, $24.75*

MICROCOUNSELING: Innovations in Interviewing, Counseling, Psychotherapy and Psychoeducation (2nd Ed.) *by* **Allen E. Ivey,** *Univ. of Massachusetts, Amherst, and* **Jerry Authier,** *Univ. of Nebraska Medical Center, Omaha. Foreword by* **Bernard G. Guerney, Jr.** *(3 Contributors)* The Second Edition of this groundbreaking introduction to interviewing and counseling updates the extensive research on the microcounseling model; presents new chapters on the cross-cultural and cross-racial implications of interviewing training; provides material illustrative of how microcounseling skills are used by various types of therapists; and includes a new section on operational definitions. The text continues to present a detailed analysis of the interview, specific methods for teaching and researching interviewing skills, and an explication of the videotape methods used in microcounseling. *'78, 624 pp., 13 il., $24.50*

SEX-RELATED COGNITIVE DIFFERENCES: An Essay on Theory and Evidence *by* **Julia A. Sherman,** *Women's Research Institute of Wisconsin, Inc., Madison.* This provocative book reviews and critically evaluates traditional theories of sex-related differences in cognitive function. Doctor Sherman also examines current methodological and conceptual problems in research. She provides up-to-date appraisals of biological theories of sexrelated differences in cognition, including X-linked theories, the hypothesis of greater male variability, metabolic and hormonal theories, and theories based on purported sex differences in brain lateralization. The latter part of the book considers theory and evidence related to sociocultural determinants. *'78, 284 pp., 7 tables, cloth-$14.75, paper-$10.95*

MAJOR MEDICINAL PLANTS: Botany, Culture and Uses *by* **Julia F. Morton,** *Univ. of Miami, Coral Gables, Florida. Forewords by* **Norman R. Farnsworth** *and* **Maynard W. Quimby.** This luxuriously produced volume describes the principal drug plants which have played an important medicinal role for many generations. Origin and geographical distribution are detailed along with areas of cultivation, yields, chemical constituents, economic uses and, where applicable, toxicity. The botany, culture, harvesting and handling of medicinal plants are explored in unprecedented depth. All plants are richly illustrated. Appendices cover those plants which provide pharmaceutical aids, and those species which have been dropped from official use in recent years. A bibliography composed of over 600 international research reports follows the text. *'78,,78, 4, 448 pp. (6 3/4 x 9 3/4), 109 il. (17 in color), 2 tables, $49.50*

THE AMERICAN JOURNAL OF PSYCHIATRY

CONTENTS Vol. 135, No. 11 November 1978

1305 The Psychodynamics and Developmental Psychology of the Borderline Patient: A Review of the Literature
Edward R. Shapiro

1316 Bilateral and Unilateral ECT: Effects on Verbal and Nonverbal Memory
Larry R. Squire and Pamela C. Slater

1321 Withdrawal Syndromes Associated with Antipsychotic Drugs
George Gardos, Jonathan O. Cole, and Daniel Tarsy

1325 Tricyclic Antidepressants: Plasma Levels and Clinical Findings in Overdose
David N. Bailey, Craig Van Dyke, Rene A. Langou, and Peter I. Jatlow

1329 Paradoxical Reaction to L-Dopa in Schizophrenic Patients
Murray Alpert, Arnold J. Friedhoff, Luis R. Marcos, and Florence Diamond

1333 The Social Context of Schizophrenia
J.K. Wing

1340 Automated Treatment for Flight Phobia: A 3½-Year Follow-up
Myron S. Denholtz, Lawrence A. Hall, and Edward Mann

1344 Coping Styles of 34 Adolescents with Cerebral Palsy
Klaus K. Minde

TOPICAL PAPERS: Future Mental Health Care Delivery Systems

1350 Mental Health Care Delivery Systems: Introduction
Benjamin Liptzin

1351 The Future for Mental Health in Primary Health Care Programs
Richard G. Morrill

1355 The Future of State Mental Health Programs for the Chronic Psychiatric Patient in the Community
Robert L. Okin

1359 Private Practice of Psychiatry: Future Roles
Zigmond M. Lebensohn

1363 Will Community Mental Health Survive in the 1980s?
Steven S. Sharfstein

1366 Mental Health Care Delivery Systems: Discussion
Boris M. Astrachan

BRIEF COMMUNICATIONS

1368 A Comparison of Depression and Physical Illness in Men and Women
Melvin L. Selzer, Maria Paluszny, and Robert Carroll

1371 Blind Ratings of Mother-Infant Interaction in Home Movies of Prepsychotic and Normal Infants
Henry N. Massie

1375 Psychological Factors in Susceptibility to Drug-Induced Extrapyramidal Symptoms
Peritz Levinson, Richard Malen, George Hogben, and Harry Smith

1377 Psychological Observations of Bank Robbery
Donald A. Johnston

1380 A Marketplace Model of Consultation Psychiatry in the General Hospital
Frederick G. Guggenheim

1384 A Look at Psychiatric Decision Making
Bruce Roberts

1388 Videotape Recording of Dynamic Psychotherapy: Supervisory Tool or Hindrance?
Claude T.H. Friedmann, Joe Yamamoto, George H. Wolkon, and Lynda Davis

1392 Psychiatry Residents in a Milieu Participatory Democracy: A Resident's View
Dennis Gersten

1396 The Relationship of Community Mental Health Centers to the Professional Standards Review Organizations Program
O.B. Towery

1399 Borderline Diagnoses
Charles L. Rich

CLINICAL AND RESEARCH REPORTS

1402 Drug History and Tardive Dyskinesia, *R.C. Smith et al*
1404 Filicide During Psychotropic-Induced Somnambulism: A Case Report, *D.J. Luchins et al*
1406 Prediction of Self-Mutilation in Hospitalized Schizophrenics, *D. Shore et al*
1407 Anticholinergic Delirium in a Case of Munchausen Syndrome, *M.H. Hollender et al*
1409 Neuroleptic-Induced Supersensitivity Psychosis, *G. Chouinard et al*

JOINT COMMISSION ON GOVERNMENT RELATIONS ..... ROBERT J. CAMPBELL

Information for Contributors

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material, have not been published previously, and are not being considered for publication elsewhere. Papers with multiple authors are reviewed with the assumption that all authors have approved them.

Copyright

The *Journal* requires express transfer of copyright to the American Psychiatric Association so that the author(s) and the Association are protected from misuse of copyrighted material. All submissions must be accompanied by a cover letter *signed by all authors* and using the following wording:

In consideration of the *American Journal of Psychiatry*'s taking action in reviewing and editing my submission [include title here] the author(s) undersigned hereby transfers, assigns, or otherwise conveys all copyright ownership to the American Psychiatric Association in the event that such work is published by the American Psychiatric Association.

Work done as part of an individual's duties as a federal employee is in the public domain. The cover letter in such cases should contain the following wording and should be signed by all authors:

The work described in [include title here] was done as part of my (our) employment with the federal government and is therefore in the public domain.

Review Process

Papers are reviewed by at least two experts to determine the originality, validity, and significance of content and conclusions. Authors will usually be advised within 2–3 months of the decision on their paper, although delays are sometimes unavoidable. Reviewers' comments will be returned with rejected manuscripts if they are judged to be useful to the authors. All reviewers remain anonymous.

Informed Consent

Manuscripts that report the results of experimental investigation with human subjects must include a statement that informed consent was obtained after the procedure(s) had been fully explained.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to John C. Nemiah, M.D., Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. All correspondence will be sent to the first-named author unless otherwise specified. Papers that are not accompanied by the appropriate cover letter, including the copyright transfer statement, will not be reviewed until such a statement is received.

Authors will be notified as soon as possible of the receipt of their paper; at this time, the paper will be assigned a number that must be included in all further correspondence. It is imperative that authors of papers under consideration notify the *Journal* of changes of address.

Annual Meeting Papers

The *Journal* has first refusal rights for numbered papers accepted for presentation at the Association's annual meetings. Authors of annual meeting papers should follow instructions they will receive in a letter from the Editor before the meeting. Annual meeting papers may be submitted for review before the meeting only if they are in *final form*, i.e., are ready for review. Authors must *not* submit their papers before the meeting if they expect any substantive revisions due to discussion at the meeting, further research, etc. These papers are subject to the same peer review criteria as other submissions, and not all papers can be published in the *Journal*. Authors who wish to submit their papers elsewhere must secure permission from the Editor. The *Journal* will assign its own number to each paper received for review; this number must appear in any further communications about the paper. The copyright transfer statement described above must accompany annual meeting papers submitted for review.

Length

The length of submitted material should not exceed the following specifications unless a special arrangement has been made with the Editor. Regular articles—3,800 words or the equivalent, including references, tables, and figures (about 15 manuscript pages). Brief Communications—2,500 words or equivalent (about 10 manuscript pages). Clinical and Research Reports—1,000 words, 10 references, 1 table (no figures can be used in this section). Letters to the Editor—500 words, 5 references. The number of words, tables, and figures should be noted on the title page.

TYPES OF ARTICLES

Overviews

Overview articles attempt to bring together important relevant information on a topic of general interest to psychiatry. They are usually written at the invitation of the Editor; authors who have ideas for overview articles are advised to check with the Editor to ensure that a similar work is not in preparation. Overviews should not exceed 25 double-spaced pages (about 7,500 words) and should have no more than 100 references. All overviews, including those written by invitation, are given the same peer review received by other papers.

Regular Articles and Brief Communications

The primary difference between these two types of papers is length. The "brief communication" designation does not imply less sophisticated or complete work: it merely means that the content can be expressed within the upper limit of 2,500 words. There is no difference in the review procedure or scheduling of these articles. Authors who submit unnecessarily long articles with redundancies and loose writing style will be asked to shorten them, which can delay publication. Authors should choose their words carefully, avoiding lengthy introductions containing material that is common knowledge, summaries that merely repeat the results, unnecessary tables, figures or references, etc. Single case reports will not be accepted as regular articles or Brief Communications; these papers should be submitted as Clinical and Research Reports.

Clinical and Research Reports

This section contains very brief articles (maximum of 1,000 words, 10 references, 1 table, and *no figures*) reporting new research findings, including preliminary data from pilot studies, and case reports that 1) describe new syndromes, 2) cast a new light on established ones, 3) indicate a new therapeutic procedure of potential value, or 4) describe adverse effects or previously unreported complications of drugs or therapeutic interventions. Because of the stringent criteria for this section, authors can expect more rapid publication than is possible in other sections. Submitted papers that substantially exceed the stated maximum length or contain figures will be returned to the author unreviewed.

Prompt Publication Policy

Articles submitted for prompt publication can be of either regular or Brief Communication length (a "prompt publication policy" is automatically in effect for Clinical and Research Reports). These papers are given priority in scheduling; however, authors should be aware that the minimum publication time is four months. Prompt publication papers must meet stringent criteria of originality, and authors must state their reasons for wanting rapid review in a cover letter to the Editor. It is important to think carefully about the nature of the paper before requesting prompt publication; a paper may be delayed if it is submitted inappropriately.

Other Sections

Letters to the Editor. Brief letters (maximum of 500 words and 5 references) will be considered if they include the notation "for publication" in the upper right corner. Letters critical of an article published in the *Journal* will automatically be sent to the authors for reply. The *Journal* is unable to notify authors of receipt of letters or to return those not published. All letters are subject to editing. Letters must be typed *double-spaced* throughout on letter-size bond paper; two copies are required. Letters that are not typed appropriately or do not conform to *Journal* reference style will be returned to the author for revision.

Book Reviews. Books for review or listing may be sent directly to the Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. Book reviews are usually solicited by the editor. Authors interested in reviewing a particular book are urged to contact the editorial office to see if the Editor wishes the book to be reviewed and to ascertain whether it has been previously assigned to another reviewer. Reviews are usually less than 500 words long, seldom contain references, and will be edited.

TYPING AND ARRANGING THE PAPER

All manuscripts must be typed in upper- and lowercase on one side only of 22 × 28 cm (8½ × 11 inches) *nonerasable* bond paper. All parts of the manuscript, including case reports, quotations, references, and tables, must be double-spaced throughout. All 4 margins must be 3¾ cm (1½ inches). The manuscript should be arranged in the following order, with each numbered item beginning a new page: 1) title page, 2) précis, 3) text, 4) references, 5) tables, 6) footnotes to text, and 7) figure captions. All pages must be numbered, with the title page as number 1. Please consult the following section on *Journal* style specifications for criteria for each part of the paper.

STYLE SPECIFICATIONS

Title Page

Title. The title should be informative but as brief as possible. Headline style (declarative sentences) should be avoided. Abbreviations and acronyms are rarely used in titles.

By-line. Authors named in the by-line should be limited to principal researchers and/or writers; collaborators can be acknowledged in a footnote. Please include degrees (other than honorary or undergraduate) after the authors' names.

Previous presentation. If the paper has been presented orally, please give the name of the meeting, the place, and inclusive dates.

Author affiliations. The authors' position titles and affiliations should be given in a paragraph using complete sentences. A full address is necessary only for the author who is to receive reprint requests.

Acknowledgments. Acknowledgments should be in a separate paragraph on the title page. Grant support should include the full name of the granting agency as well as the grant number. Individual acknowledgments should be as brief as possible. Acknowledgments of companies that supplied drugs are used only in the case of experimental drugs or those unavailable in this country.

Other requirements. The number of words, tables, and figures should appear in the upper right corner and a phone number for the corresponding author in the lower right.

Précis

The précis should be up to 100 words for regular articles and Brief Communications (no précis is used in the Clinical and Research Reports section). The précis should be a single paragraph using complete, connected sentences, active verbs, and the third person. In most cases, the précis replaces a summary.

Text

Headings and subheadings should be inserted at reasonable intervals in all types of papers. Footnotes to text material should be typed on a separate page at the end of the manuscript. Summaries are rarely desirable, although a final "Comment" or "Conclusions" section may be used. The body of the paper should be written in the active voice and first person where appropriate.

Statistics. Authors should be sure that statistics used are both necessary and appropriate. Statistical tests should be described and a reference citation given if the tests are not generally known. It is not sufficient to say "differences between the groups were significant." In cases of lengthy complicated analyses, the authors may summarize results and indicate that details are available from them on request.

Abbreviations. All abbreviations (other than those for metric units) should be explained the first time they are used. Idiosyncratic abbreviations should be avoided: overuse of abbreviations may hinder rather than facilitate readability.

Drugs. Generic rather than trade names of drugs should be used; trade names may be given parenthetically if necessary.

Units of measurement. All measurements should be in metric units; standard abbreviations are used.

References

References should be restricted to closely pertinent material; a complete review of the literature is rarely desirable. *Accuracy of citation is the author's responsibility.* References should conform exactly to the original spelling, accents, punctuation, etc. Authors should be sure that all references listed have been cited in text; no bibliographies can be used.

References are numbered and listed by their order of appearance in text; the text citation is followed by the appropriate reference number in parentheses. Do *not* arrange the list alphabetically.

Personal communications, unpublished manuscripts, manuscripts submitted but not yet accepted, and similar unpublished items should not appear in the reference list. Such citations may be noted in text or in a footnote. It is the author's responsibility to obtain permission to refer to another individual's unpublished observations. Manuscripts that are actually "in press" may be cited as such in the reference list; the name of the journal must be included.

Type references in the style shown below and on the next page, double-spaced *throughout* (not just a line between references). List up to three authors; designate one or more authors past the third "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*; journals not indexed there should not be abbreviated.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26

2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968

Tables

Tables should be self-explanatory and should supplement rather than duplicate text. Authors may be asked to delete tables that present data which could be given succinctly in text or repeat information in the Results section. Tables are generally reserved for data presentation and not used as lists or charts. They should be no wider than 120 typewriter characters, including spaces. Consult recent issues of the *Journal* for table style. Please note that no vertical rules or internal horizontal rules are used. It is usually desirable to give both numbers and percentages where applicable. All units of measurement must be specified within the table. Metric measurements are used in tables and throughout the text. Each table should be identified numerically and include a concise title.

Figures

Figures should be used only for data that cannot be adequately presented in text or tabular form. Figures should be submitted as glossy prints with one photocopy attached to each manuscript copy. The author's name and the title of the paper should appear on a gummed label affixed to the back of each glossy. All figures should be able to withstand reduction to about 8 cm (3¼ inches). Authors are urged to consider carefully the necessity of figures; they may be asked to delete figures that repeat information available in text. It is often advisable to obtain professional assistance in the preparation of figures.

PROCESSING OF ACCEPTED MANUSCRIPTS

Authors will be notified of acceptance of their papers; papers will then be edited and sent to the first-named (or corresponding) author for corrections and answers to editorial queries. No galley proofs are sent to authors, so the edited manuscript should be read with extreme care. Prompt return of edited manuscripts is essential. Authors who expect to be away from their offices for a long period or who change address after notification of acceptance should so inform the *Journal* office.

Manuscripts are accepted with the understanding that the Editor has the right to make revisions aimed at greater conciseness, clarity, and conformity with *Journal* style.

PERMISSION TO REPRINT

Written permission to reprint material published in the *Journal* must be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for such permission, except in cases of nonprofit use for educational purposes or of an author who wishes to reprint his/her own material. Requests will be facilitated if they are accompanied by written permission from the author of the material.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article. Reprint orders from others should be directed to the APA Publications Services Division; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

The December 1978 issue of

The American Journal of Psychiatry

will feature

- Genetic Counseling for Psychiatric Patients and Their Families

  By Ming T. Tsuang

Hallucinations... delusions... thought disorders... controlled

Navane (thiothixene) rapidly controls hallucinations as well as the agitation and hostility patterns they frequently generate.

Rapid control of psychotic symptoms on admission

Navane provides effective, rapid control of the major symptoms of psychosis including hallucinations, delusions, agitation, hostility, and thought disorders.[1-5] Navane promotes rapid progress, usually without the over-sedation or cardiovascular problems that can impede the therapeutic course.

Continued long-term improvement

Because Navane provides long-term outpatient control of psychotic symptoms, it can enable many patients to function effectively at home and on the job and to adjust rapidly to the community.[6]

Effectiveness rarely compromised by adverse reactions

Navane allows patients to remain alert and active, seldom causing over-sedation or drowsiness.[7] Hypotension and other cardiovascular reactions[5,6,8] are seldom reported and the occurrence of unpleasant anticholinergic side effects such as dry mouth or constipation is rare.[9] If extrapyramidal symptoms occur, they are usually readily controlled through dosage adjustments or antiparkinson agents.

Rapid control
Long-term improvement

Navane®

(thiothixene) (thiothixene HCl)

Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. Concentrate 5 mg./ml. Intramuscular 2 mg./ml.

For prescribing information, including adverse reactions and contraindications, please see following page of this advertisement.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg
(thiothixene hydrochloride) Concentrate: 5 mg/ml.
Intramuscular: 2 mg/ml

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*—Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration—As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

As an organization accredited for Continuing Medical Education, The Institute of Pennsylvania Hospital certifies that this continuing medical education activity meets the criteria for 24 credit hours in Category I of the Physicians Recognition Award of the American Medical Association provided it is used and completed as designed.

DEVELOPMENT

This 24 credit Category I course was designed by the Director and the Office of Continuing Education of the Institute of Pennsylvania Hospital. In the first stage of development, topic selection was confirmed by a nationwide sampling of 900 practicing psychiatrists. The director then invited seven outstanding psychiatrist/teachers to prepare lessons in their areas of recognized expertise. The published material will be tightly structured and clearly presented. At the conclusion of the course, comments and views of the participants will be published so that everyone can further benefit from a shared learning experience.

EDUCATIONAL OBJECTIVE

The objective of this continuing medical education program is to provide an opportunity for the practicing psychiatrist to assess and further develop his own clinical skills by means of a home study program sponsored by the Institute of Pennsylvania Hospital. This first program will present in depth six topics of current interest and clinical usefulness and will include a series of questions designed to aid this assessment and to focus his reading. If he chooses, the psychiatrist may select additional articles for further study and may also develop a written dialogue with the editors for further discussion.

TEXT

24 lessons will be published in monographs of four lessons each and mailed monthly. Each lesson is followed by a series of questions structured to bring content and learning level into focus.

COMPUTER RESPONSE

The sophisticated computer response form not only presents scores and averages for personal and confidential peer comparison but in the case of a wrong answer will indicate sources of correct information both in the text and in key references. The questions and answers are keyed to the computer, personalizing responses while maintaining confidentiality. Our unique procedures encourage the development of a dialogue between the course participant and the editors.

COST

$210 tax deductible tuition covers total cost of materials and postage including custom binder, return envelopes and continuously updated material where required.

For depressed patients who must function effectively in daily activities...

PAMELOR®
(nortriptyline HCl) NF
25mg. Capsules

Patients remain alert.

Most depressed patients must function effectively in their daily activities, on the job or at home. For these patients, PAMELOR capsules may be an appropriate therapeutic choice. PAMELOR relieves depression, yet rarely causes daytime drowsiness. As with all antidepressants, however, patients should be cautioned against driving or operating hazardous machinery.

Insomnia of depression begins to improve within a week.

PAMELOR capsules are effective for relieving insomnia, a cardinal symptom of depressive illness. Patients begin to sleep better within the first week of therapy. The full therapeutic effect of PAMELOR is usually observed by the second week.

PAMELOR therapy is well tolerated.

In 90 studies, a total of 818 patients were treated with PAMELOR capsules. Of the patients who improved completely or markedly, over half (54%) had no side effects. Those who experienced side effects most commonly complained of dry mouth.

For Brief Summary please see last page of this advertisement.

SANDOZ
PHARMACEUTICALS
EAST HANOVER, N.J. 07936

PAMELOR®
(nortriptyline HCl) NF
25 mg. Capsules

The antidepressant for the patient who must remain alert and active.

- relieves depression without causing problem daytime drowsiness
- insomnia of depression begins to improve within a week
- PAMELOR therapy is well tolerated

Indications: For relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Hypersensitivity. Should not be given concomitantly with MAO inhibitors or within 2 weeks of the use of this drug since hyperpyretic crises, severe convulsions, and fatalities have occurred when similar tricyclic antidepressants were used in such combinations. Cross-sensitivity with other dibenzazepines is a possibility. Contraindicated during acute recovery period after myocardial infarction.

Warnings: Use with caution in patients with cardiovascular disease because of tendency to produce sinus tachycardia and prolong conduction time. Myocardial infarction, arrhythmia, and strokes have occurred. May block antihypertensive action of guanethidine and similar agents. Because of anticholinergic activity, use cautiously in patients with glaucoma or a history of urinary retention. Patients with a history of seizures should be followed closely because the drug is known to lower the convulsive threshold. Great care is required for hyperthyroid patients and those taking thyroid medication because of possible development of cardiac arrhythmia. Caution patients about possibility of impaired mental and/or physical ability to operate a motor vehicle or dangerous machinery. Response to alcoholic beverages may be exaggerated and may lead to suicidal attempts. Safe use during pregnancy, lactation, and women of childbearing potential has not been established and the drug should not be given unless clinical situation warrants potential risk. Not recommended for use in children.

Precautions: Psychotic symptoms may be exacerbated in schizophrenic patients. Increased anxiety and agitation may occur in overactive or agitated patients. Manic-depressive patients may experience shift to manic phase. Hostility may be aroused. Concomitant administration of reserpine may produce a "stimulating" effect. Watch for possible epileptiform seizures during treatment. Use cautiously with anticholinergic or sympathomimetic drugs. Concurrent electroconvulsive therapy may increase hazards associated with nortriptyline HCl. When possible, discontinue drug several days prior to surgery. Potentially suicidal patients require supervision and protective measures during therapy. Prescriptions should be limited to the least possible quantity. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: The pharmacologic similarities among the tricyclic antidepressant drugs require that each of the following reactions be considered when nortriptyline is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia, panic, nightmares; hypomania; exacerbation of psychosis.

Neurologic: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alteration in EEG patterns; tinnitus.

Anticholinergic: Dry mouth and rarely, associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue), drug fever, cross-sensitivity with other tricyclic drugs.

Hematologic: Bone-marrow depression, including agranulocytosis; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black-tongue.

Endocrine: Gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness, fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though these are not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Dosage and Administration: *Usual adult dose* – 25 mg. three or four times daily; dosage should begin at a low level and increase as required. As an alternate regimen, the total daily dosage may be given once-a-day. *Elderly and Adolescent* - 30 to 50 mg. per day, in divided doses, or the total dosage may be given once-a-day. Doses above 100 mg. per day and use in children are not recommended. If a patient develops minor side effects, the dosage should be reduced. The drug should be discontinued promptly if adverse effects of a serious nature or allergic manifestations occur.

How Supplied: Capsules 10 mg. and 25 mg.; solution 10 mg./5 cc.

For more detailed information see full prescribing information.

Sex Education for the Health Professional

A CURRICULUM GUIDE

Edited by NORMAN ROSENZWEIG, M.D. and F. PAUL PEARSALL, Ph.D.

A *Seminars in Psychiatry* Monograph
Milton Greenblatt, M.D., Series Editor

Sex Education for the Health Professional is the first attempt to bring together in a systematic fashion the various pedagogical approaches of contemporary leaders in sex education as they relate to the training and work of health care professionals. The contributors represent the largest assemblage of outstanding, universally recognized sex educators to be found within the covers of a single volume.

The book is intended to help those planning an education program in human sexuality for health professionals to develop a curriculum and approach to the subject—and to help those already conducting such courses to review, evaluate and improve their current efforts. Designed to facilitate discussions and examinations of the several dimensions of sexuality curriculum, the volume will serve as a medium for sharing ideas and orientations toward such curricula.

Haldol®
(haloperidol)
tablets/concentrate/injection

Promptly controls psychotic symptoms... usually leaving the patient alert and productive

Highly effective in a wide range of both acute and chronic psychotic disorders,[1-7] such as hallucinations, delusions, suspiciousness, hostility, mania.

Permits aggressive titration to effective dosage levels for optimal response.[1,4]

Facilitates prompt initiation of other therapeutic efforts... and often helps avoid hospitalization.[1-3]

Minimal risk of hypotension, oversedation, or troublesome anticholinergic effects.[2,4-6,8,9] Transient hypotension occurs rarely; severe orthostatic hypotension has not been reported. Although some instances of drowsiness have been reported, marked sedation is rare.

Common side effects easily controlled.[1,2,4-7] Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

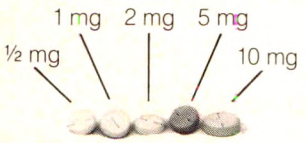
*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Please turn page for summary of prescribing information.

concentrate

A tasteless, odorless, colorless liquid concentrate for better patient compliance: 2 mg per ml.



injection

A rapid-acting injection for psychiatric emergencies: 5 mg per ml,* with 1.8 mg methylparaben and 0.2 mg propylparaben per ml, and lactic acid for pH adjustment to 3.4 ± 0.2.

tablets

5 tablet strengths for convenience in individualizing dosage:

HALDOL® (haloperidol)

tablets / concentrate / injection

A dosage form for every therapeutic need

Summary of Prescribing Information

Contraindications: Severe depression, coma, CNS depression due to centrally-acting depressants, Parkinson's disease, hypersensitivity to the drug.

Warnings: ***Usage in Pregnancy:*** Safe use in pregnancy or in women likely to become pregnant has not been established; use only if benefit clearly justifies potential hazards. Infants should not be nursed during drug treatment.

Usage in Children: Safety and effectiveness not established; not recommended in pediatric age group.

Combined Use With Lithium: Patients receiving lithium plus haloperidol should be monitored closely for early evidence of neurological toxicity.

General: Bronchopneumonia, sometimes fatal, has followed use of major tranquilizers, including haloperidol. Prompt remedial therapy should be instituted if dehydration, hemoconcentration or reduced pulmonary ventilation occurs, especially in the elderly. Decreased serum cholesterol and/or cutaneous and ocular changes have been reported with chemically-related drugs, although not with haloperidol. Mental and/or physical abilities required for hazardous tasks or driving may be impaired. Alcohol should be avoided due to possible additive effects and hypotension.

Precautions: Administer cautiously to patients: (1) with severe cardiovascular disorders, due to the possibility of transient hypotension and/or precipitation of anginal pain (if a vasopressor is required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur); (2) receiving anticonvulsant medication since HALDOL haloperidol may lower the convulsive threshold; (3) with known allergies or a history of allergic reactions to drugs; (4) receiving anticoagulants. Concomitant antiparkinson medication, if required, may have to be continued after HALDOL haloperidol is discontinued because of different excretion rates; if both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson drugs, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used for mania in cyclic disorders, there may be a rapid mood swing to depression. Severe neurotoxicity may occur in patients with thyrotoxicosis receiving antipsychotic medication, including HALDOL haloperidol.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions:* Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which were usually mild to moderately severe and usually reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally, extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Antiparkinson drugs may be required. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases.

Withdrawal Emergent Neurological Signs: Abrupt discontinuation of short-term antipsychotic therapy is generally uneventful. However, some patients on maintenance treatment experience transient dyskinetic signs after abrupt withdrawal. In certain cases these are indistinguishable from "Persistent Tardive Dyskinesia" except for duration. It is unknown whether gradual withdrawal will reduce the occurrence of these signs, but until further evidence is available haloperidol should be gradually withdrawn.

Persistent Tardive Dyskinesia: Although rarely reported with HALDOL haloperidol, tardive dyskinesia may appear during or after long-term therapy. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and sometimes appear irreversible; there is no known effective treatment and all antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent.

Other CNS Effects: Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms.

Cardiovascular Effects: Tachycardia and hypotension. ***Hematologic Effects:*** Reports of mild, usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis; agranulocytosis rarely reported and only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice reported. ***Dermatologic Reactions:*** Maculopapular and acneiform reactions, isolated cases of photosensitivity, loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

The injectable form is intended only for acutely agitated psychotic patients with moderately severe to very severe symptoms.

Caution: Federal law prohibits dispensing without prescription.

Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

HALDOL tablets are manufactured by McNeil Laboratories Co., Dorado, Puerto Rico 00646.

Divide scored Endep tablets

+

Add flexibility to dosage titration

Long term treatment of depression with amitriptyline requires precise calculation of dosage to meet the individual needs of each patient. Because all six strengths of Endep are scored, you can easily increase or decrease dosage in half-tablet steps, without the bother and expense of a new prescription.

−

Subtract waste and cost

Scored Endep tablets permit you to adjust the regimen without wasting unused tablets or burdening the patient with the cost of a new prescription.

×

Multiply therapeutic options

The pharmacokinetic properties of Endep are such that its clinical effect is the same whether prescribed *t.i.d.* or as a single daily dose. Thus, once you have established the proper dosage, you can prescribe the entire dose *h.s.*, minimizing anticholinergic and sedative side effects, and helping to assure patient compliance with this simple regimen.

By prescribing the higher strength tablets *h.s.*—secure in the knowledge that the dosage can be adjusted without resorting to a new prescription—your patient will economize further on a per milligram basis.

Endep®
amitriptyline HCl/Roche

The only antidepressant scored for easy division

Endep
amitriptyline HCl/Roche

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle-closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh possible benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.

Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Supplied: *Scored Tablets:* 10, 25, 50, 75, 100, 150 mg.

The Schizophrenic Disorders

Long-Term Patient and Family Studies

Manfred Bleuler
translated by Siegfried M. Clemens

The long-awaited English translation of Manfred Bleuler's classic study of schizophrenics conducted over the course of more than two decades. Bleuler's ground-breaking research focuses on cross-generational factors of schizophrenia and the risks of its transmission, drawing important comparisons between onset patterns, disease-course types, and the enigmatic implications of hereditary versus environmental factors for schizophrenic development.

"This massive study by the renowned Swiss psychiatrist [makes] a major scientific contribution to the field."

The Brown Schools: Specialists in Residential Treatment

Residential treatment has become highly specialized in the field of mental health. It is a specific treatment modality for those who need a totally planned and structured environment.

The Brown Schools has developed a wide range of professional services that can be utilized to implement an individually planned residential treatment program. The degree of structure and protection, the intensity of therapy, the methods of education and training are controlled and modified with the resident's changing needs.

Professionals in the areas of psychiatry, psychology, nursing, social work, education, prevocational training, speech pathology, and recreation have developed expertise in the specific area of residential treatment. Each service area is designed as a component of an integrated therapeutic milieu.

The three residential treatment centers of The Brown Schools provide complete programming for those in need of twenty-four hour care. Services are available for children, adolescents, and adults with emotional disturbance, mental retardation, and neurological impairment. Two small group homes in Austin provide for reintegration into the community and complement the services offered in the other centers. For information, write:

Helps weather
the manic storm
maintenance therapy with
Eskalith®
brand of
lithium carbonate
300 mg capsules

Helps weather the manic storm

In manic-depressive patients with a history of mania, 'Eskalith'

- **prevents or diminishes the intensity of future episodes**
- **can increase the intervals between episodes**
- **helps patients function within normal limits**

maintenance therapy with Eskalith® brand of lithium carbonate

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

WARNING
Lithium toxicity is closely related to serum lithium levels, and can occur at doses close to therapeutic levels. Facilities for prompt and accurate serum lithium determinations should be available before initiating therapy.

Indications: Treatment of manic episodes of manic-depressive illness. Maintenance therapy prevents or diminishes the intensity of subsequent episodes in manic-depressive patients with a history of mania.

Warnings: Lithium should generally not be given to patients with significant renal or cardiovascular disease, severe debilitation or dehydration, sodium depletion, or to patients receiving diuretics.

Caution patient and family to watch for diarrhea, vomiting, tremor, mild ataxia, drowsiness, or muscular weakness as signs of lithium toxicity, and to discontinue therapy and contact a physician should they occur. Patients receiving combined therapy with lithium and an antipsychotic should be monitored closely for early evidence of neurologic toxicity and treatment discontinued promptly if such signs appear. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery).

Lithium should not be used in pregnancy, especially during the first trimester, unless potential benefits outweigh possible hazards.

Not recommended for children under 12.

Precautions: Lithium tolerance is greater during the acute manic phase and decreases when manic symptoms subside.

Lithium therapy may lead to sodium depletion. Normal diet (including salt) and adequate fluid intake (2500-3000 ml.) must be maintained, at least during initial stabilization period. Protracted sweating or diarrhea can decrease tolerance; in such cases, administer supplemental fluid and salt.

Sweating, diarrhea, and concomitant infection with elevated temperatures may require temporary reduction or cessation of dosage.

Adverse Reactions: Mild to moderate toxic reactions may occur at serum lithium levels from 1.5 to 2.5 mEq./1., and moderate to severe reactions at levels from 2.0 to 2.5 mEq./1. Fine hand tremor, polyuria, and mild thirst may occur during initial therapy and persist. Transient and mild nausea and general discomfort also appear during initial therapy. These effects usually subside with continued treatment or temporary reduction or cessation of dosage. If persistent, discontinue dosage.

Diarrhea, vomiting, drowsiness, muscular weakness, and lack of coordination may be early signs of toxicity and may occur at levels below 2.0 mEq./1. At higher levels, ataxia, giddiness, tinnitus, blurred vision, and a large output of dilute urine may be seen. Serum levels above 3.0 mEq./1. may produce a complex clinical picture, involving multiple organs and systems. Serum levels should not exceed 2.0 mEq./1. during acute phase.

The following reactions appear to be related to serum lithium levels, including levels within the therapeutic range: **Neuromuscular**—tremor, muscle hyperirritability (fasciculations, twitching, clonic movements of whole limbs), ataxia, choreo-athetotic movements, hyperactive deep tendon reflex; **Central Nervous System**—blackout spells, epileptiform seizures, slurred speech, dizziness, vertigo, incontinence of urine or feces, somnolence, psychomotor retardation, restlessness, confusion, stupor, coma; **Cardiovascular**—cardiac arrhythmia, hypotension, peripheral circulatory collapse; **Gastrointestinal**—anorexia, nausea, vomiting, diarrhea; **Genitourinary**—albuminuria, oliguria, polyuria, glycosuria; **Dermatologic**—drying and thinning of hair, alopecia, anesthesia of skin, chronic folliculitis, exacerbation of psoriasis, xerosis cutis; **Autonomic**—blurred vision, dry mouth; **Thyroid Abnormalities**—euthyroid goiter and/or hypothyroidism (including myxedema) with lower T_3 and T_4. I^{131} uptake may be elevated; **EEG Changes**—diffuse slowing, widening of the frequency spectrum, potentiation and disorganization of background rhythm; **EKG Changes**—reversible flattening, isoelectricity of inversion of T-waves; **Miscellaneous**—fatigue, lethargy, transient scotomata, dehydration, weight loss, tendency to sleep.

Reactions unrelated to dosage include: transient EEG and EKG changes, leukocytosis, headache, diffuse nontoxic goiter with or without hypothyroidism, transient hyperglycemia, generalized pruritus with or without rash, cutaneous ulcers, albuminuria, worsening of organic brain syndromes, excessive weight gain, edematous swelling of ankles or wrists, thirst or polyuria, sometimes resembling diabetes insipidus, and metallic taste. A single case of a syndrome resembling Raynaud's has been reported.

How Supplied: 300 mg. capsules in bottles of 100.

CALM
AND
ALERT*
THE
PATIENT ON
VERSTRAN®
(prazepam)
C-IV

Smooth, consistent anxiolytic action is the reason.

Proven efficacy

- Effective symptomatic relief of anxiety, whether psychic or somatic in origin
- Therapeutic response achieved with first dose
- Verstran—a suitable antianxiety alternative to diazepam

Established safety

- Virtually no drowsiness* in most Verstran patients (less than 10%)
- Other side effects, if present, are minimal†
- Verstran is appropriate concomitant therapy in most somatic disorders‡
- No accumulation after steady state is reached

Dosage versatility

- The simplicity of a single-strength 10-mg scored tablet, for easy titration and improved patient compliance
- The flexibility of *once daily*§ dosage
- The option of a *b.i.d.* dosage regimen, gradually adjustable within a range of 20 to 60 mg/day

*As with all CNS-acting agents, patients should be cautioned against driving, drinking, or engaging in hazardous activities.

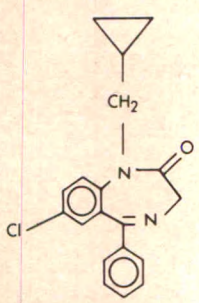
§At bedtime.



TO ENHANCE PATIENT RESPONSIVENESS CONSIDER

VERSTRAN (prazepam) Ⓒ IV

VERSTRAN® (prazepam) Ⓒ IV

Caution: Federal law prohibits dispensing without prescription.

Description: Verstran (prazepam), a benzodiazepine derivative, is identified chemically as 7-chloro-1-(cyclopropylmethyl)-1,3-dihydro-5-phenyl-2H-1,4-benzodiazepin-2-one. The molecular weight is 324.8 and the structural formula is as follows:

Clinical Pharmacology: Studies in normal subjects have shown that Verstran (prazepam) has depressant effects on the central nervous system. Oral administration of single doses as high as 60 mg and divided doses up to 100 mg t.i.d. (300 mg total daily dose) were without toxic effects.

Single oral doses of Verstran in normal subjects produced peak blood levels at 6 hours postadministration, with significant amounts still present after 48 hours. Verstran was slowly absorbed over a prolonged period, rather constant blood levels were maintained, and excretion was prolonged. The mean half-life of prazepam measured in subjects given 10 mg t.i.d. for one week was 63 (±15 s.d.) hours before and 70 (±10 s.d.) hours after multiple dosing — a nonsignificant difference. Human metabolism studies showed that prior to elimination from the body, prazepam is metabolized in large part to 3-hydroxyprazepam and oxazepam.

Indications: Verstran (prazepam) is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

The effectiveness of Verstran (prazepam) in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

Contraindications: Verstran (prazepam) is contraindicated in patients with a known sensitivity to the drug and in those with acute narrow angle glaucoma.

Warnings: Verstran (prazepam) is not recommended in psychotic states and in those psychiatric disorders in which anxiety is not a prominent feature.

Patients taking Verstran should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery, including motor vehicles.

Because Verstran has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, including phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. The effects of alcohol may also be increased.

Physical and Psychological Dependence: Withdrawal symptoms similar in character to those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepine drugs. These symptoms include convulsions, tremor, abdominal and muscle cramps, vomiting and sweating. Addiction-prone individuals, such as drug addicts and alcoholics, should be under careful surveillance when receiving benzodiazepines because of the predisposition of such patients to habituation and dependence.

Precautions:

Use in Pregnancy and Lactation:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. Verstran (prazepam) a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug. In view of their molecular size, Verstran and its metabolites are probably excreted in human milk. Therefore, this drug should not be given to nursing mothers.

In those patients in whom a degree of depression accompanies the anxiety, suicidal tendencies may be present, and protective measures may be required. The least amount of drug that is feasible should be available to the patient at any one time.

Patients taking Verstran for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed. Hepatomegaly and cholestasis were observed in chronic toxicity studies in rats and dogs.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

Pediatric Use: Safety and effectiveness in patients below the age of 18 have not been established.

Adverse Reactions: The side effects most frequently reported during double-blind placebo-controlled trials employing a typical 30 mg divided total daily dose and the percent incidence in the Verstran (prazepam) group were: fatigue (11.6%), dizziness (8.7%), weakness (7.7%), drowsiness (6.8%), lightheadedness (6.8%), and ataxia (5.0%). Less frequently reported were: headache, confusion, tremor, vivid dreams, slurred speech, palpitation, stimulation, dry mouth, diaphoresis, and various gastrointestinal complaints. Other side effects included: pruritus, transient skin rashes, swelling of feet, joint pains, various genitourinary complaints, blurred vision, and syncope. Single nightly dose, controlled trials of variable dosages showed a dose-related incidence of these same side effects. Transient and reversible aberrations of liver function tests have been reported, as have slight decreases in blood pressure and increases in body weight.

These findings are characteristic of benzodiazepine drugs.

Overdosage: As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

If vomiting has not occurred spontaneously, it should be induced. Immediate gastric lavage is also recommended. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though unlikely, may be controlled with Levophed® (levarterenol bitartrate) or Aramine® (metaraminol bitartrate). Caffeine and Sodium Benzoate Injection, USP, may be used to counteract central nervous system depressant effects.

Dosage and Administration: Verstran (prazepam) is administered orally in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 20 to 60 mg daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a divided daily dose of 10 mg to 15 mg. (See Precautions.)

Prazepam may also be administered as a single dose daily at bedtime. The recommended starting nightly dose is 20 mg. The response of the patient to several days' treatment will permit the physician to adjust the dose upward or, occasionally, downward to maximize antianxiety effect with a minimum of daytime drowsiness. The optimum dosage will usually range from 20 to 40 mg.

Drug Interactions: If Verstran (prazepam) is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If Verstran is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

How Supplied: Verstran (prazepam) 10 mg light blue, scored tablets in bottles of 100 (N 0047-0276-51) and 1000 (N 0047-0276-60).

STORE BETWEEN 59°–86° F (15°–30° C).

The Joint Information Service of the American Psychiatric As and the Mental Health Association releases Two New Volum

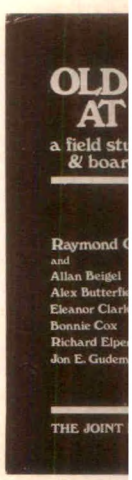
Focus on the Elderly

This carefully documented book reports a field study of ten programs and six in England and Scandinavia, which serve as practical de creative mental health services for the elderly. They include:

- a novel "Neighborhood Family" providing vigorous support to elc several trailer parks
- a high school for the elderly which sends its students abroad for
- a "Human Development Project" that focuses on responding to t needs of the elderly
- a carefully coordinated system of "respite hospitalization," whi health of the elderly while allowing maximum use of hospital beds and
- a "Lucy Booth," patterned after the Peanuts comic strip, whic access to many kinds of services
- and many other innovative, successful approaches.

Each program is subjected to intensive scrutiny. The resulting docu handbook, and, as well, a forum through which some of the world's n practitioners of "the psychiatry of old age" present their views.

Dr. Wilma Donohue, director of the International Center for Soc characterizes this volume as "a masterful job of putting everything guidelines for action are right here."



190 pages. Casebound. Price $8.50.

Concerned about the very bad reputation that nursing homes have received from many quarters in recent years, the Joint Information Service set up a field study to visit a systematically chosen sample of nursing homes, and board-and-care homes as well, to see to what extent the care of and the quality of life for the patients differed from the geriatrics units of state hospitals. Altogether, sixty nursing homes and 31 board-and-care homes in ten locales were visited, in each case by the senior author accompanied by two mental health professionals.

The teams were surpised to learn that care and quality of life in many of the nursing and board-and-care homes they visited were better—sometimes dramatically better—than that in the mental health facilities and often at lower cost.

This unique publication provides an overview of all facilities visited plus vignettes of approximately half. Federal and state rules and regulations are also expertly synthesized into brief and readable style.

148 pages. Casebound. Price $6.50

One way to evaluate seizure etiology

Computerized transaxial tomography (CT scan) is an important new noninvasive technique that can help in determining the etiology of epileptic seizures. Shown here is a single slice from a color-enhanced CT scan of the brain of a patient with epilepsy. The absence of vascular abnormalities, tumor, or other lesions is compatible with a diagnosis of idiopathic epilepsy.

A proven way to start seizure control

MYSOLINE®
(primidone) Tablets 50 mg, 250 mg Suspension 250 mg/5 ml

A single entity with multiple anticonvulsant properties

Primidone itself has anticonvulsant activity. In addition, its major metabolite, phenylethylmalonamide (PEMA), exerts an anticonvulsant effect of its own and also enhances the anticonvulsant action of the second metabolite, phenobarbital. In patients refractory to phenytoin and phenobarbital, primidone may prove effective as the sole therapy.[1]

Multiple indications—grand mal, psychomotor, and focal epileptic seizures

In grand mal, MYSOLINE is comparable in efficacy to phenytoin and phenobarbital.[2,3] In psychomotor seizures, phenobarbital is rarely effective.[1] In focal seizures, phenytoin used alone is not indicated[4]—and, according to Forster,[3] MYSOLINE is markedly more effective than phenobarbital, which should dispel the misconception that MYSOLINE is "just a phenobarbital." (See chart below.)

Efficacy ratings* of anticonvulsants in epilepsy

Agent	Grand Mal	Psychomotor	Focal
Mysoline	++++	++++	++++
Hydantoinates (phenytoin)	++++	+++	+++
Barbiturates (phenobarbital)	++	++	++

*Relative effectiveness, ++++ being most effective.
Adapted from Forster, F. M.[3]

Consider it first for major motor epilepsies

MYSOLINE® (primidone) Ayerst®

See next page for Brief Summary and references.

Start seizure control with MYSOLINE® (primidone)

Initial dose in children over 8 years of age and adults: 250 mg daily at bedtime

BRIEF SUMMARY
(For full prescribing information, see package circular.)
MYSOLINE®
Brand of **PRIMIDONE** *Anticonvulsant*

ACTIONS: MYSOLINE raises electro- or chemoshock seizure thresholds or alters seizure patterns in experimental animals. The mechanism(s) of primidone's antiepileptic action is not known.

Primidone *per se* has anticonvulsant activity as do its two metabolites, phenobarbital and phenylethylmalonamide (PEMA). In addition to its anticonvulsant activity, PEMA potentiates that of phenobarbital in experimental animals.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several weeks before it can be assessed.

Usage in pregnancy: The effects of MYSOLINE in human pregnancy and nursing infants are unknown.

Recent reports suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Data are more extensive with respect to diphenylhydantoin and phenobarbital, but these are also the most commonly prescribed anticonvulsants; less systematic or anecdotal reports suggest a possible similar association with the use of all known anticonvulsant drugs.

The reports suggesting an elevated incidence of birth defects in children of drug-treated epileptic women cannot be regarded as adequate to prove a definite cause and effect relationship. There are intrinsic methodologic problems in obtaining adequate data on drug teratogenicity in humans; the possibility also exists that other factors, *e.g.*, genetic factors or the epileptic condition itself, may be more important than drug therapy in leading to birth defects. The great majority of mothers on anticonvulsant medication deliver normal infants. It is important to note that anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that the removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus.

The prescribing physician will wish to weigh these considerations in treating or counseling epileptic women of childbearing potential.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

PRECAUTIONS: The total daily dosage should not exceed 2 g. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 g per day. The initial dose is 250 mg. Increments of 250 mg are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 g. A typical dosage schedule for the introduction of MYSOLINE is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg daily at bedtime	*2nd Week* 250 mg b.i.d.
3rd Week 250 mg t.i.d.	*4th Week* 250 mg q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg, with gradual weekly increases of 125 mg a day, to a daily total usually between 500 mg and 750 mg.

In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances: for initiation of combination therapy; during "transfer" therapy; for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.).

HOW SUPPLIED: MYSOLINE Tablets—No. 430—Each tablet contains 250 mg of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg of primidone (scored), in bottles of 100 and 500.
MYSOLINE Suspension—No. 3850—Each 5 ml (teaspoonful) contains 250 mg of primidone, in bottles of 8 fluidounces.

ROCHE

How to Initiate and Maintain Therapy

Select dosage strength appropriate for each patient

- Limbitrol 10-25 is recommended for most patients
- Limbitrol 5-12.5 may be indicated for those who do not tolerate higher doses and for elderly patients

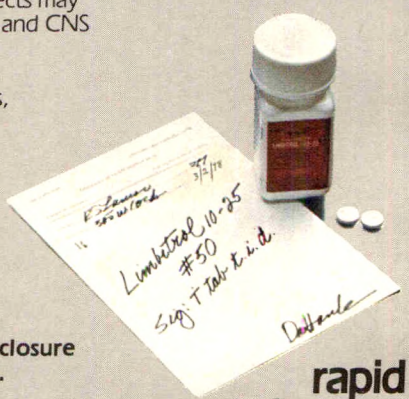
Specify daily dosage based on symptom severity

- An initial dosage of three tablets is recommended
- Dosage may be increased to six tablets or decreased to two tablets daily as necessary
- Once a satisfactory response is obtained, evaluate response, and if necessary, reduce dosage to smallest amount needed to maintain remission

Utilize dosage options to best accommodate individual patient needs

- T.I.D. or Q.I.D., familiar regimens best suited for patients who tolerate medication without undue drowsiness
- Two tablets one hour before bedtime and one tablet midday may minimize daytime drowsiness and help relieve a common target symptom—insomnia
- Entire dosage h.s. to take maximum advantage of the sedative effect

How to make each patient an informed patient



1. Discuss with patients the probability that they will experience drowsiness, especially during the first week.
2. Reassure your patients that drowsiness is one indication that the medication is working and that it may help alleviate their insomnia.
3. Encourage patients to report if drowsiness becomes troublesome so that, if necessary, dosage schedule can be adjusted or the symptom treated.
4. Caution patients about the combined effects with alcohol or other CNS depressants. Let them know that the additive effects may produce a harmful level of sedation and CNS depression.
5. Caution patients about activities requiring complete mental alertness, such as operating machinery or driving a car.
6. Warn pregnant patients and patients of childbearing age that the safety of Limbitrol in pregnancy has not yet been established.

Please see complete product disclosure for other pertinent information.

Limbitrol should not be used under the following circumstances

1. Hypersensitivity to benzodiazepines or tricyclic antidepressants.
2. Should not be given with an MAO inhibitor. To replace an MAO inhibitor with Limbitrol, discontinue MAO inhibitor for a minimum of 14 days before cautiously initiating Limbitrol therapy.
3. During the acute recovery phase following myocardial infarction.

Limbitrol

For rapid relief of moderate to severe depression and anxiety

LIMBITROL® TABLETS
Tranquilizer–Antidepressant

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Relief of moderate to severe depression associated with moderate to severe anxiety.
Contraindications: Known hypersensitivity to benzodiazepines or tricyclic antidepressants. Do not use with monoamine oxidase (MAO) inhibitors or within 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Contraindicated during acute recovery phase following myocardial infarction.
Warnings: Use with great care in patients with history of urinary retention or angle-closure glaucoma. Severe constipation may occur in patients taking tricyclic antidepressants and anticholinergic-type drugs. Closely supervise cardiovascular patients. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, especially high doses. Myocardial infarction and stroke reported with use of this class of drugs.)

Usage in Pregnancy: **Use of minor tranquilizers during the first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Since physical and psychological dependence to chlordiazepoxide have been reported rarely, use caution in administering Limbitrol to addiction-prone individuals or those who might increase dosage; withdrawal symptoms following discontinuation of either component alone have been reported (nausea, headache and malaise for amitriptyline; symptoms [including convulsions] similar to those of barbiturate withdrawal for chlordiazepoxide).
Precautions: Use with caution in patients with a history of seizures, in hyperthyroid patients or those on thyroid medication, and in patients with impaired renal or hepatic function. Because of the possibility of suicide in depressed patients, do not permit easy access to large quantities in these patients. Caution patients about possible combined effects with alcohol and other CNS depressants and against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Periodic liver function tests and blood counts are recommended during prolonged treatment. Amitriptyline component may block action of guanethidine or similar antihypertensives. Concomitant use with other psychotropic drugs has not been evaluated: sedative effects may be additive. Discontinue several days before surgery. Limit concomitant administration of ECT to essential treatment. See Warnings for precautions about pregnancy. Limbitrol should not be taken during the nursing period. Not recommended in children under 12.
In the elderly and debilitated, limit to smallest effective dosage to preclude ataxia, oversedation, confusion or anticholinergic effects.
Adverse Reactions: Most frequently reported are those associated with either component alone: drowsiness, dry mouth, constipation, blurred vision, dizziness and bloating. Less frequently occurring reactions include vivid dreams, impotence, tremor, confusion and nasal congestion. Many depressive symptoms including anorexia, fatigue, weakness, restlessness and lethargy have been reported as side effects of both Limbitrol and amitriptyline. Granulocytopenia, jaundice and hepatic dysfunction have been observed rarely.
This list includes adverse reactions not reported with Limbitrol but requiring consideration because they have been reported with one or both components or closely related drugs:
Cardiovascular: Hypotension, hypertension, tachycardia, palpitations, myocardial infarction, arrhythmias, heart block, stroke.
Psychiatric: Euphoria, apprehension, poor concentration, delusions, hallucinations, hypomania and increased or decreased libido.
Neurologic: Incoordination, ataxia, numbness, tingling and paresthesias of the extremities, extrapyramidal symptoms, syncope, changes in EEG patterns.
Anticholinergics: Disturbance of accommodation, paralytic ileus, urinary retention, dilatation of urinary tract.
Allergic: Skin rash, urticaria, photosensitization, edema of face and tongue, pruritus.
Hematologic: Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia.
Gastrointestinal: Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, black tongue.
Endocrine: Testicular swelling and gynecomastia in the male, breast enlargement, galactorrhea and minor menstrual irregularities in the female and elevation and lowering of blood sugar levels.
Other: Headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, jaundice, alopecia, parotid swelling.
Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. I.V. administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestation and treatment.
Dosage: Individualize according to symptom severity and patient response. Reduce to smallest effective dosage when satisfactory response is obtained. Larger portion of daily dose may be taken at bedtime. Single *h.s.* dose may suffice for some patients. Lower dosages are recommended for the elderly.
Limbitrol 10-25, initial dosage of three to four tablets daily in divided doses, increased up to six tablets or decreased to two tablets daily as required. Limbitrol 5-12.5, initial dosage of three to four tablets daily in divided doses, for patients who do not tolerate higher doses.
Supplied: Limbitrol 10-25 tablets each containing 10 mg chlordiazepoxide and 25 mg amitriptyline (as the hydrochloride salt) and Limbitrol 5-12.5 tablets each containing 5 mg chlordiazepoxide and 12.5 mg amitriptyline (as the hydrochloride salt)—bottles of 100 and 500, Tel-E-Dose® packages of 100; Prescription Paks of 50.

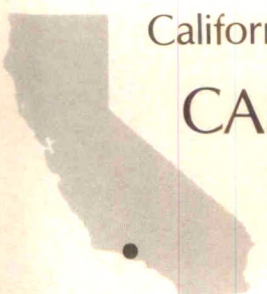
NEW IN THE CONTEMPORARY COMMUNITY HEALTH SERIES from Pittsburgh

THE DOCTOR TREE:
DEVELOPMENTAL STAGES
IN THE GROWTH OF PHYSICIANS
by Ralph N. Zabarenko and Lucy M. Zabarenko $9.95
Not satisfied with the present, often exclusive emphasis of medical schools on knowledge and training, the authors propose that education for doctors be viewed as an intertwining of development and training. They single out five developmental lines that help to produce the professional identity we call "a physician."

DISCOVERING SUICIDE: STUDIES
IN THE SOCIAL ORGANIZATION
OF SUDDEN DEATH
by J. Maxwell Atkinson $14.95
This strongly written and personalized study challenges the basic assumptions on which most conventional approaches to suicide are based. Dr. Atkinson presents the question of how suicides are identified, pointing out the apparent convergence between commonsense and "scientific" methods of reasoning. He concludes that the sociological approach known as ethnomethodology is best suited to solve the problems involved.

SOCIAL SKILLS AND MENTAL HEALTH
by Peter Trower, Bridget Bryant, and Michael Argyle $12.95
In the past ten years, new theories and discoveries in the social sciences have given a scientific basis and new impetus to the development of social-skills training as a form of therapy. This book explores the progress made with this treatment and gives practical guidance for therapists based on the authors' experience.



Also New From Pittsburgh

FREUD'S EARLY PSYCHOLOGY OF THE
NEUROSES: A HISTORICAL PERSPECTIVE
by Kenneth Levin $12.95
In this masterful historical study, Kenneth Levin explores Freud's early work on the neuroses. He defines more comprehensively than anyone has before the origins of Freud's interest in these diseases, the development of his early theories from 1886 to 1900, and the relationship of Freud's views to relevant concepts current in nineteenth-century neurology, psychiatry, and psychology.

A FESTERING SWEETNESS:
POEMS OF AMERICAN PEOPLE
by Robert Coles $5.95 paper $20.00 limited edition
The renowned child psychiatrist and author takes a new approach—creating verse forms which readily capture the hopes, fears, and expectations of the deprived in the United States. Dr. Coles's extraordinary sensitivity of ear and eye is reminiscent of the doctor-writer tradition of William Carlos Williams.

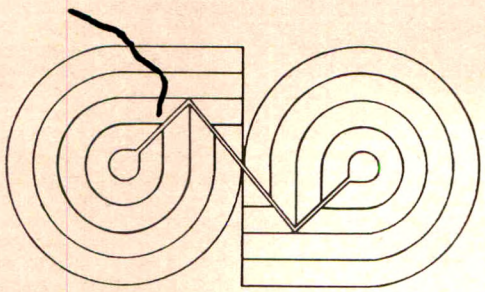
Psychiatric Associateships at National Institute of Mental Health

The National Institute of Mental Health Associate Program at the National Institutes of Health is offering two or three year Associateships for intensive training in virtually all areas of clinical and basic psychobiological research. The program is currently approved for a third year of residency training. Applicants should be in their last year of training or should have completed training by the start of the appointment and should be U.S. citizens or eligible for naturalization within four years of the expected appointment date. Applications are due by January 15, 1979 for appointments which begin July 1980.

Excellent facilities are available at The Clinical Center on the 306-acre NIH campus in Bethesda, Maryland, and at nearby St. Elizabeth's Hospital in Washington, D.C. Clinical Associates are assigned clinical responsibility in caring for patients who are admitted for both therapeutic and research purposes. Research Associates engage in laboratory research under the preceptorship of one of the senior staff and may participate in tutorial seminars and other teaching programs.



A competitive salary is available for candidates qualifying for appointment in the Commissioned Corps, United States Public Health Service. A portion of the salary is tax exempt. Moving and travel expenses are paid and health care is free.

PKSAP-III

PSYCHIATRIC KNOWLEDGE AND SKILLS SELF-ASSESSMENT PROGRAM

CONTINUOUS OFFERING

PKSAP-III is again available. The Program, initially available to physicians in Spring/Summer, 1977, will differ in that central scoring services will not be provided. Each registrant will receive the question booklets, the Reference guidebook containing the correct answers and bibliography, a score worksheet, and the Performance Data Report, which will facilitate self-scoring, follow-up reading and study at the participant's convenience. For further program details, the Bulletin of Information, is available upon request to the APA, Office of Education.

To register, remit the appropriate fee with this application form to the APA, PUBLICATIONS SALES. PLEASE MAKE CHECKS PAYABLE TO APA, PKSAP-III.

a consideration beyond efficacy alone...

Infrequent akathisia and other disabling extrapyramidal effects...

The rapidly rising readmission rate among discharged psychotic patients is mainly due to noncompliance with antipsychotic drug therapy. And this, in turn, may be largely attributed to disabling extrapyramidal side effects, notably akathisia.[1]

Although extrapyramidal effects are characteristic of antipsychotic agents in general, with Mellaril (thioridazine) such effects are infrequent. Adding an antiparkinsonian agent—which can cause its own side effects—can usually be avoided. Mellaril (thioridazine) is contraindicated in patients with severe hypotensive or hypertensive heart disease.

Extrapyramidal Effects of Selected Antipsychotic Agents*[2]

DRUG	EXTRAPYRAMIDAL EFFECTS
Chlorpromazine	Moderate
Perphenazine	High
Prochlorperazine	High
Fluphenazine	High
Acetophenazine	Moderate
Trifluoperazine	High
Chlorprothixene	Moderate
Thiothixene	Moderate
Haloperidol	High
MELLARIL® (thioridazine)	Low

*Based on antipsychotic dosage ranges

Mellaril® (thioridazine)

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP
CONCENTRATE: 100 mg per ml

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.
Store and dispense Concentrate below 86°F; use tight, amber glass bottle. Just prior to administration, Concentrate may be diluted with distilled water, acidified tap water, or suitable juices; preparation and storage of bulk dilutions is not recommended.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.
It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

THE AMERICAN JOURNAL OF PSYCHIATRY

The Psychodynamics and Developmental Psychology of the Borderline Patient: A Review of the Literature

BY EDWARD R. SHAPIRO, M.D.

The author reviews the psychodynamics and developmental psychology of the borderline patient as described in the literature on intensive therapy, early mother-child interaction, and family interaction. Focusing on the borderline patient's characteristic difficulties in intimate relationships, he describes the patient's use of splitting and projective identification as seen in the characteristic transference-countertransference interaction in intensive therapy. These primitive defensive mechanisms, which are also utilized by family members, appear to contribute to a failure of empathic responses both during the child's early development and in the family interactions during his adolescence. The author concludes that conceptual attempts to relate adult and child phenomena, although highly speculative, create new and useful perspectives for the treatment of the borderline patient.

THERE IS a growing body of work on the dynamics and developmental psychology of the borderline patient. The literature springs from three main sources: observations of the transference-countertransference interaction in intensive psychotherapy or analysis, observation of the preverbal infant in interaction with his mother, and study of the family in interaction. Despite the active controversy about the nondefinitive boundaries of the diagnostic classification of borderlines (1–3) and the continual attempts to reach bett[illegible] diagnoses (4), clinicians have found [illegible] clarity about the underlying dynamic [illegible] mental issues of great use in wor[illegible] therapeutically with these patients and [illegible] ing and putting into perspective the ter[illegible] velop in the work.

In this paper I will survey the major [illegible] ture and attempt to synthesize the curre[illegible] ing of the many dynamic and developme[illegible] volved. The literature is large and is fi[illegible] condensed metapsychological abstracti[illegible] resent attempts to make sense of subt[illegible] data. I will attempt, when possible, to [illegible] concepts into clinical language without [illegible] sary violence to the complexity of the [illegible]

The focus of the review will be on [illegible] patient's characteristic difficulties in int[illegible] ships (5). There are specific element[illegible] psychopathology that engage both [illegible] and therapists in unique ways. I will a[illegible] these observations as they have bee[illegible] both the dynamic and the developmen[illegible]

CONTRIBUTIONS OF DESCRIPTIVE PSYCHOLOGICAL STUDIES

Although the attempt to apply a des[illegible] to the presence and frequency of sym[illegible] observable abnormal behavior of the [illegible] tient is important (2, 4, 6), it may be [illegible] of the characteristic behavioral and [illegible] sponses of these patients seem to app[illegible] of stress, while at other times the pa[illegible] tively asymptomatic (7). Nonetheless [illegible] from descriptive studies and from re[illegible] logical test reports are congruent wit[illegible] vations from intensive therapy.

Gunderson (4) and Grinker and We[illegible]

Written at the invitation of the Editor.

Dr. Shapiro is Assistant Clinical Professor of Psychiatry, Harvard Medical School, Boston, Mass., and Director, Adolescent and Family Treatment and Study Center, McLean Hospital, Belmont, Mass. 02178.

The author would like to thank Drs. Leon Shapiro, Shervert Frazier, Roger Shapiro, Susan Abelson, and Peter Panzarino, and Diane Englund, A.C.S.W., for their helpful comments on an earlier draft of this paper.

most discriminating data in their descriptive studies to be in the observation of the difficulties borderline patients have in interpersonal relationships, particularly in terms of their pervasive sense of aloneness and their tendency to see difficulties as emanating from outside themselves. Gunderson[1] suggested from his data that these attributes, as well as an inability to acknowledge wants and to discriminate them from needs, are "core conflicts" in borderline patients.

On unstructured projective tests that provide the opportunity for regressive responses, borderline patients reveal evidence of primary process thinking (7), a strong tendency to add too much and too specific affect to simple perceptions, and a propensity to produce these peculiar responses without concern or embarrassment. Margaret Singer's review of series of test reports (8) revealed that these responses do not occur on more structured tests, suggesting that these patients can utilize an external organizing structure to support their thinking. This finding has been corroborated by repeated clinical observations (2, 9–11). Melvin Singer (12) suggested the presence of a cognitive disturbance in which these patients fail to structure, delay, detour, and check their impulses and affects through "cognitive binding" (i.e., through contemplation, fantasy, reflection, and symbol formation).

These findings suggest that borderline pathology is related to difficulties in the management of impulse and affect, which is perceived most characteristically in interpersonal relationships and emerges most clearly in relatively unstructured settings. The intensive, relatively unstructured therapeutic relationship, then, is an ideal setting in which to study in detail the elements of the disorder.

TRANSFERENCE DEVELOPMENT AND PROBLEMS

The response of borderline patients in intensive therapy is characteristically marked by gross fluctuations in perception, thinking, and feeling about themselves and the therapist, without awareness of the contradictions (13, 14). Margaret Singer (8) found this tolerance and bland acceptance of contradictory thoughts a unique attribute of these patients.

Kernberg (7) described the borderline patient as having little capacity for realistic appraisal of others and, in the absence of a relationship, as experiencing others as distant objects to whom he can compliantly adapt. In therapy borderline patients present narrow, rigid, unmodulated affects (15) and show little ability to tolerate guilt, concern, or internalized depressive affect (16, 17). They have difficulty in discriminating and reporting body sensations and emotions (13) and manifest little capacity for anxiety or frustration tolerance, delay, or impulse control (7). Their unpleasant affects readily escalate to panic without triggering reliable defensive operations (18), and they manifest a profound sense of identity diffusion, with little sense of inner continuity from past to present to future (15). Unlike the majority of psychotic patients, they are capable of higher level defenses and good reality testing in many situations, but they are likely to regress to transient psychotic states under stress or within the transference relationship, readily developing fantasies of extreme neediness, destruction, and abandonment (7, 19).

The transference of the borderline patient has been described as immediate, intense, and chaotic, only gradually developing over time into discernible patterns (7, 15). Modell (20–22) described the patient's diagnostic transference response to the therapist as similar to the infant's response to the "transitional object" (e.g., blanket or teddy bear). He suggested that although the patient recognized the therapist as existing outside the patient (as is not the case in the transference of many psychotic patients), the quality of this perceived existence is determined by processes arising within the patient. Although neurotic patients also attribute certain qualities of their own to a therapist, they seem to have the capacity to recognize the origins of these perceptions within themselves, while borderline patients do not (5).

The transference response described by Modell is seen most clearly in the borderline patient's difficulty in asking the therapist for help in a way that would imply an acknowledgment that the therapist as a separate person might reasonably refuse or be unable to respond to the request. For the borderline patient, to consider the possibility of the therapist's refusal is to become aware of anxious, rage-filled fantasies of abandonment that are perceived as potentially arising from the therapist. To avoid these fantasies, the patient does not ask directly for help. Instead, he either angrily demands a response or overtly ignores the therapist in the session while maintaining an illusion of comfort from the therapist's presence. This response is seen as similar to the child's response to his blanket.

Winnicott (23) described the child's blanket as something that possesses attributes of its own (warmth, texture, something "not me") yet is not allowed to change unless changed by the child. It is "used" by the child—both loved and mutilated—and must survive both (24). As in the therapeutic relationship described by Modell, the blanket is not "asked" for help. It is, instead, symbolically placed as a protective shield between the child and the dangers of the outside world; the child is comforted by it. Several authors (23, 25–27) have described the relationship with the transitional object as representing a phase in the child's gradual separation from his mother, a gradual disengagement in which the blanket partly represents his mother (and the child) and partly represents the outside world. Abelin (28) described the father as occupying this position during the child's separation-individuation period.

[1]Gunderson JG: Discriminating characteristics of borderlines and their families (unpublished paper, 1977).

In the early stages of therapy, some borderline patients use inanimate objects, animals, or certain fantasies as transitional ways of relating to the therapist, metaphorically putting these objects between them and the therapist both to protect them from a dangerous intimacy and simultaneously to allow a relationship to exist (25, 26).

Borderline patients demonstrate their characteristic unmodified, polarized responses in the therapeutic relationship (15, 22). They have magical expectations from therapy, often anticipating improvement without their own active participation. They may experience the therapist as benevolent but demonstrate the constant fear that he or she will be transformed into the opposite. Under stress, they may experience the therapist as attacking and may fear that they will be dominated, controlled, or abandoned by him (19, 29). In the latter experiences they feel alone, helpless, and needy and appear unable to maintain a reliable sense that the therapist remains with them in a caring way (19). Because of these tensions, they present the manifest conflict of extreme dependence and intense fear of closeness, the solution to which appears to be a constant preoccupation with maintaining the "proper" distance from the therapist in order to regulate their anxiety about both distance and closeness.

EGO DEFENSES

The use of specific primitive ego defenses has been described as characteristic of the borderline patient in intimate relationships. Kernberg (7, 30), in describing the borderline patient's disjointed, contrasting behaviors and fantasies in intensive therapy, suggested that there is an underlying pattern of sharply polarized fantasied relationships that is "activated" in the transference. The polarization of these fantasies is determined by the defensive maneuver labeled "splitting." Kernberg suggested that borderline patients' core difficulty lies in their inability to bring together and integrate loving and hating aspects of both their self-image and their image of another person. Kernberg's observation was that these patients cannot sustain a sense that they care for the person who frustrates them. Kernberg saw this characteristic failure in the achievement and tolerance of ambivalence and in the modification of affects as diagnostic. He suggested that loving fantasied relationships and hating ones are internally "split" for the borderline patient to prevent the anxiety that would result if they were experienced simultaneously. These positive or negative stereotyped fantasies are activated in a relationship depending on the degree of gratification or frustration perceived by the patient. In a gratifying relationship, the patient develops positive fantasies, with the negative ones dissociated or "split off" and therefore unavailable. When frustrated, the patient elaborates negative fantasies and loses all memory of the positive relationship.

Other authors (1, 4, 13, 31, 32) ha[illegible] comfortable with the idea of splitting [illegible] mechanism for borderline patients. Mo[illegible] acknowledge the patient's failure to [illegible] modify impulses and affects as an imp[illegible] istic.

Splitting as a defense is to be distin[illegible] nial, which is the disavowal of whole ob[illegible] substitution of a wish-fulfilling fanta[illegible] sion, which is the repulsion of menta[illegible] consciousness due to a linkage of that [illegible] conflicted memory (33). In splitting, th[illegible] negative fantasied relationships remai[illegible] consciousness with the complement[illegible] ated.

Defensive splitting also contributes t[illegible] alternating view of the therapist as on[illegible] valued. In these responses to the thera[illegible] experiences no real dependency on h[illegible] love or concern. Instead, the patient [illegible] sudden shift from total need to total de[illegible]

A second major defense of borderline [illegible] associated with both splitting and trans[illegible] ness, is that of projective identificatio[illegible] defense involves the dissociation of [illegible] pects of the personality (elements of i[illegible] age, or superego) and the projection o[illegible] other person, resulting in an identific[illegible] other person because of having attribu[illegible] the self to him. Included in this intrap[illegible] personal mechanism, particularly for [illegible] tients, is the unconscious attempt to [illegible] behavior in the other that conform w[illegible] and the willingness (conscious or not) [illegible] of these projections to accept these at[illegible] of himself (32).

The person using this defense [illegible] attentive to the real aspects of the oth[illegible] tradict or invalidate the projection. [illegible] the other (now seen as possessing the [illegible] acteristics) is consciously identified as [illegible] (36), while an unconscious relationship [illegible] which the projected attribute can be vi[illegible] rienced.

This defense differs from projection [illegible] vidual maintains some contact with the [illegible] jected. The projections are not simply [illegible] other; an unconscious attempt is mad[illegible] relationship with the other and to invol[illegible] lusive partner in conforming to the v[illegible] perceived (37, 40).

Projective identification is a defens[illegible] spectrum of psychopathology from norm[illegible] ic. The severity of the pathology is det[illegible] content of the projection, the capacity [illegible] test reality and to differentiate himse[illegible] person, and the intensity of the subj[illegible] need to avoid conflict by disavowing a [illegible] of himself. Depending on the interactio[illegible] tors, projective identification can end[illegible]

ship with emphatic qualities or create a delusional distortion and give a binding quality to the interaction (38).

Of central importance in the borderline patient's use of this defense are its consequences in terms of a weakening of his or her ego functioning. Klein (34) noted that projection of aggressive aspects of the self may result in a loss of attributes important for the development of power, potency, strength, and knowledge. Kernberg (30) suggested that the resultant failure of integration leads to incomplete development of internalized standards (e.g., guilt and internal delay of impulses) and other internal "structures" (18).

Similarly, according to Klein (34), the chronic projection of positive aspects of the self (as seen in primitive idealization) may result in extreme dependency, loneliness, fear of parting, and fear of the loss of the capacity to love. Kernberg (7) suggested that the borderline patient's use of idealization in its primitive form involves no regard for the real person who is idealized but represents a use of the other as a "thing"—an "all positive" magical protection in a dangerous world (3, 7).

The borderline patient has been described as having a peculiar "empathy" for the unconscious impulses of other people (41, 42) and as having little or no ability to recognize the mature defenses, reaction formations, or other adaptive ego functions manifested by the other person in his struggle with these impulses (7, 43). This intuitive sensitivity allows for a powerful coercive use of projective identification because there is often some degree of perceptual accuracy in the projection that touches a conflicted area of the recipient. When frustrated and projecting their anger in therapy, for instance, borderline patients may utilize this intuition to provoke a response in such a way as to justify their distrust and may then destroy, devalue, or reject all the therapist has to offer (44).

COUNTERTRANSFERENCE

The use of these primitive defenses contributes to the transference-countertransference difficulties often seen in intensive treatment. Many authors have described the powerful countertransference responses evoked by the borderline patient (11, 13, 14, 19, 20, 22, 45). Unlike the more gradually developed, complex, empathic understanding that characterizes his or her response to neurotic patients, the therapist's response to the borderline patient's transference appears to be more rapid, intense, and stereotyped. Different therapists discover similar responses to these patients; the response seems less related to specific problems of the therapist's past and more to the patient's poorly integrated impulses (7).

Because of their defensive inability to integrate loving and angry aspects of the same internal image, borderline patients are inordinately sensitive to minor frustrations in treatment. In the face of such frustrations, their characteristic response is to withdraw all affectively positive perceptions of the therapist and reinvest them elsewhere. At this point, patients "lose" all memory of positive experiences with the therapist and feel abandoned. Through the mechanism of projective identification, they experience the therapist as attacking and rejecting and respond defensively to control their now projected rage (46). Their defensive response may include rage, devaluation, withdrawal, or paranoid thinking and an inability to call up the previously experienced image of a comforting therapist (19).

If the therapist exposed to these raw affective interchanges undergoes an "empathic regression" (7) in an attempt to keep in touch with the patient, he may become vulnerable to countertransference guilt and anxiety. Many therapists who have devoted their lives to healing are concerned at some level about their capacity to hurt, which borderline patients unconsciously sense. In his introspective attempt to understand the patient, the therapist might find a punitive aspect of himself at whom the patient might "accurately" be angry. Such a counteridentification might evoke guilt in the therapist which, when perceived by the patient, would validate the patient's projection, making it difficult for the therapist to work on it collaboratively with the patient as a projection (46, 47). This blurring of ego boundaries between patient and therapist might contribute to the familiar regressive transference psychosis in which patients' reality testing is lost, their unmodified rage and guilt increase, and they experience the therapist as a reincarnation of the fantasied early frustrating parent.

Similarly, the unexpected and uncontrolled intensity of the patient's rage may make the therapist vulnerable to his own anxiety, which is potentially disruptive to the therapeutic work. Such anxiety in the therapist could be related to the possible loss of the relationship with the patient (with specific countertransference implications) or the need to manage his own hatred and need to retaliate (45, 48). In response to these countertransference feelings, Kernberg (7) suggested that otherwise sophisticated therapists may at times experience an almost masochistic submission to the patient's aggression, disproportionate doubts in their own capacity, and exaggerated fears of criticism by third parties.

In their description of the therapeutic task with borderline patients, several authors have discussed the need for the therapist to withstand these unmodified affects without withdrawal or retaliation. The therapeutic position is characterized as the provision of a "holding environment" (49), a response that includes the need 1) to reflect, absorb, transform, and feed back the patient's responses (7), 2) to maintain contact, concern, and emotional availability (50), 3) to set limits for the patient to help him or her manage internal and external stimuli, and 4) to accept the patient's ambivalence with continuing concern (19). This description of the therapeutic response in situations in which inter-

pretation appears to have no effect (51) has its parallels in the developmental observations described below.

OBJECT RELATIONS THEORY

Much of the data derived from the above observaitons has been used by theorists in the development of object relations theory (7, 21, 33, 52–55). The basic assumption behind this theory is that one can understand the relationships between people through an examination of the internal images they have of one another. In the healthiest people, these images correspond rather accurately to the reality of the other person and are continually reshaped and reworked as new information is perceived and integrated. In less psychologically healthy people, the images are stereotyped, rigid, and relatively unchanged by new information. The theory proposes a model for the developmental shaping of these images as the child begins to separate the image of himself from that of his mother. Anna Freud (56) characterized this developmental line as proceeding from dependency to emotional self-reliance to adult relationships.

According to the theory, there are at least three major developmental tasks in this progression: 1) self-object differentiation, 2) the integration of loving and hating images and the development of object constancy, and 3) the further integration of these images into flexible psychic structures (for example, superego and ego ideal).

These ideas are based primarily on clinical observations of transference relationships with psychotic, borderline, and neurotic patients and are inferentially related to early child development. Self-object differentiation refers to the child's capacity to separate intrapsychically the boundaries of his own experience from his experience of his mother. Failure in this task is presumably seen in psychotic patients who have difficulty in recognizing the therapist's independent existence. The attainment of object constancy (or the "depressive position") (16, 34) is a consequence of the child's capacity to recognize himself simultaneously as both loving and hating in response to the image of another who is both gratifying and frustrating. Accomplishment of this task presumably allows the child to tolerate and master separation and loss by being able to maintain a comforting image of the mother (a "constant object image") despite her frustrating the child by her absence (11, 56). Further, the capacity to acknowledge angry feelings toward the image of a loved person leads to the development of the capacity for reality testing and the capacity to tolerate guilt, concern, and "internalized depression" (11, 56). "Internalized depression" in this sense refers to an experience of mourning and regret over lost "good" internal images, rather than the more primitive sense of impotent rage and defeat by external forces (7). Failure in this achievement of object constancy is presumably characteristic of borderline patients who have mastered self-object differentiation but ca[illegible] ol[illegible] separation or ambivalence without regre[illegible]

This object relations view of borderline [illegible]ology of interest in that it suggests a basis for [illegible] object constancy. Presumably, the child [illegible] strong enough image of his positive rel[illegible] his mother to be able to tolerate the inte[illegible] images of negative interactions with his [illegible] out being overwhelmed. Kernberg (7, [illegible] that this failure of integration and the [illegible] splitting is due to excessive aggression, [illegible] tutional or from excessive or chronic [illegible] mental frustration.

Horner (57) described the person who [illegible] these tasks as "a separate individual w[illegible] sense of self and other, who is able to [illegible] as whole persons rather than simply [illegible] who can tolerate ambivalence . . . and [illegible] ability to sustain his own narcissistic ec[illegible] resources within the self." Further integ[illegible] cation, and "depersonification" of thes[illegible] relationships evolves into such psychic [illegible] superego and ego ideal (7, 30).

DEVELOPMENTAL PSYCHOLOGY

Many psychoanalytically oriented re[illegible] study preverbal infant development foc[illegible] tion on the intimate mother-child relatio[illegible] of particular interest to the student of [illegible] chopathology. The literature, howeve[illegible] warnings about the dangers of direc[illegible] from infant observations to adult phen[illegible] Since the infant has a unique cognitive [illegible] little capacity for conscious memory a[illegible] bolization, it has been suggested that th[illegible] er's inferences are likely to be distort[illegible] spective falsifications and adultomorph[illegible] pathy" (62). Several observers (63, 64) h[illegible] that the closest one can get to preverba[illegible] the adult patient is that which is filte[illegible] fantasies of the oedipal period, when [illegible] tal and verbal capacities begin to app[illegible] closely those of the adult. Theodor[illegible] warned of the danger of the "great or[illegible] which suggests that the first year of lif[illegible] what follows that its stamp is irrepara[illegible] the alternative hypothesis that each [illegible] stage presents a new opportunity for [illegible] zation that allows earlier experiences [illegible] toxic.

Others (34, 54, 65) have argued that [illegible] ness of the infant's mental apparatus a[illegible] all-encompassing internal struggle to d[illegible] self from a symbiotic unity with the m[illegible] such a core, global, organizing expe[illegible] traces must be seen (particularly if u[illegible] subsequent stages. At the very least, [illegible] derived from this struggle seem to be a[illegible]

petitive dynamic issues with which the borderline patient struggles.

As described above, the clearest, most comprehensive formulation about the relationship between borderline psychopathology and developmental psychology is that of Kernberg (30) and the object relations theorists (54). Kernberg suggested that borderline pathology is a consequence of a developmental failure occurring after self-object differentiation but before the development of object constancy. He described this failure as marked by a continuing defensive use of splitting, with resultant limitations in the capacity to test reality, to tolerate anxiety and frustration, and to sustain a stable, integrated relationship with an underlying attitude of basic trust (7, 46).

This formulation is apparently applicable to a large number of borderline patients, but it has been questioned by some authors, who have found two discernible groups or at least two different qualities of experience within the borderline population. These two qualities are variously described as schizoid versus aggressive (19), constricted versus expansive (12), compliant versus aggressive (13), obsessive ("as-if," "false self") versus hysterical (66), and "those who have given up" versus "those who are still searching" (3). Although Kernberg's formulation appears to apply to the second group in each of these pairs, it does not seem adequately to describe members of the first group, with their distant, "pseudoautonomous" functioning and their difficulty in engaging the other in anything but a compliant manner (13). Clearer formulations about both groups emerge from the developmental data of the symbiotic and separation-individuation periods (ages 0–3), when the issues of intrapsychic separation and the development of formed images first appear.

Symbiotic Period

Mahler (6) described the symbiotic period as extending from the second month (when the infant begins tactilely and visually to explore the mother) to the fifth month (when the infant begins to explore beyond the mother). She defined this period as characterized by the infant's acting as though his internal experience of himself and his mother were joined by a common boundary with no recognition of separateness.

During this period the tasks of the mother are to satisfy the infant's needs, to buffer and modify the stimuli he receives (both internal and external), and in effect to act as an auxiliary ego. Preparation for these tasks is facilitated by a regression in the mother (49, 68) that increases her empathy, reawakens fantasies of her own childhood experiences, and helps develop her capacity to provide a "holding environment" (49) in which the infant's "absolute need for empathy" is met.

Mahler (67) described the "mutual cuing" that must take place between infant and mother for normal symbiosis to take place. The infant's contribution to this interaction requires attributes of both perceptual ability (i.e., the capacity to receive and seek nurturance and attachment and to link patterns of experience) and stimulus sensitivity (i.e., sensitivity to touch and visual responses). The mother's tasks require her recognition and acceptance of her own infantile impulses, with a resultant continuing empathic responsiveness to similar impulses in her child.

Unacknowledged conflict in the mother in interaction over time with specific attributes of the child may result in an empathic failure that interferes with this "optimal symbiosis." Some authors (39, 42, 57, 69–71) have suggested that in such situations the infant may prematurely inhibit his dependency on his mother in order to respond to her defensive needs, a response that may result in premature ego development. Failure in the mother-child interaction during this period has been suggested as the origin of pathology for the first quality of experience within the borderline spectrum (i.e., the "pseudoautonomous" complaint, detached response).

If, for example, because of unconscious conflict about her own needs, the mother disavows them, sees them as "bad," and projects them onto her child, she may persistently withdraw from or be relatively unresponsive to the child's actual needs because of the confusion with hers (projective identification). Several authors have suggested that such chronic nonresponsiveness is experienced by the child as a meaningless interruption, resulting in his eventual detachment (39, 70, 71) and formation of a "false self" (51) in which the child compliantly adapts to his mother's needs with relative abandonment of his own, since they represent a threat to a mother whom the child absolutely needs and who is relatively immune to his feedback (70).

This detached self is the consequence of a premature severing of the symbiotic tie before any internalization of maternal functions can occur. It leaves the child with a sense of detachment (72), a profound emptiness, and an undeveloped potential for the direct and personal experience of living (70). It is a distancing maneuver, presumably developed by the child to ward off the negative experience of the mother's chronic empathic failure and misinterpretation. The pseudoself is that which validates the mother's projection (70). According to Friedman (70), Winnicott suggested that the failure of interpretation in the therapy of patients with such false self-organization is due to their perception of the interpretation as another "act of attribution" by a nonempathic parent.

Separation-Individuation

Mahler and associates (27) divided the separation-individuation period (5 months–3 years) into four subphases: 1) differentiation (5–8 months), 2) "practicing" (8–16 months), 3) rapprochement (16–25 months), and 4) object constancy (25 months–3 years). Within this period the child's task is to emerge gradually from the symbiotic unit and to develop increasing autonomy both internally and externally. Successful

completion of this developmental period results in the capacity for frustration tolerance, the mastery of separation anxiety, and the maintenance of self-esteem.

It is during these subphases of separation-individuation that the issues central to the dynamics of borderline psychopathology first appear. It is here that the conflict between the push for autonomy and the wish to unite is for the first time apparent in the behavior of the child.

During the differentiation subphase (5–8 months), the child remains anchored to the mother but develops an increasing alertness, an outer orientation, and finally, a social smile that increasingly focuses on the mother (59, 73). In her absence the child gets restless and unhappy, but he smiles on her return. This fact suggests the initial development of "recognition memory": the ability for perception to revive a memory trace (73, 74).

At 8 months the infant develops "stranger anxiety." Mahler and associates (27) observed that if there is a good symbiotic period the infant reacts to strangers with curiosity and wonderment; if it is less good the infant demonstrates more anxiety. These observations are congruent with Kernberg's formulation (30) that a greater quantity of frustration during symbiosis would threaten the infant's loving experiences, resulting in a prolonged defensive splitting and projection of fearsome negative experience onto the "stranger."

In the "practicing" subphase (5–16 months), the infant develops the capacity for locomotion with an exuberance and excitement that temporarily enables him to ignore the presence of his mother. Exhausted by autonomous movements, the infant periodically returns to the mother for "emotional refueling" (27), a brief contact that rapidly enables the infant to restore his or her energy and momentum. During this subphase there is evidence that the child begins to notice and tolerate his mother's departure, since he tones down his activities ("low keyedness") in her absence (27).

Kernberg (7, 30) suggested that the child begins to be able to differentiate between positive images of himself and his mother during this period; similar self-object differentiation within images of negative experiences occur somewhat later. He suggested, however, that this differentiation of images is still tentative at this point and vulnerable to "regressive refusion" at times of stress.

The rapprochement subphase (16–25 months) is the period during which the conflict between autonomy and reunion is demonstrated most clearly in the child's behavior and response. Even the language of the descriptions evokes images familiar to therapists of borderline patients. It is in this phase that the toddler's behavior indicates a sense of increased separateness, loneliness, helplessness, a constant concern with the mother's presence, and increased separation and stranger anxiety. It is during this period, according to Kernberg (7, 30), that the child develops firm boundaries between the experience of himself and that of his mother. The infant now responds to [illegible] fueling place, he responds to *her*.

Observers of the child in this subp[illegible] scribed the toddler's active interest [illegible] presence and his developing need for [illegible] tively in his autonomous achievemen[illegible] noted two normal patterns: shadowing [illegible] and darting away expecting to be swep[illegible] Inferred from this behavior is both th[illegible] ion and the fear of engulfment.

In children who have difficulties [illegible] phase, Mahler (58) observed increase [illegible] havior manifested by rapidly alterna[illegible] and repudiation of the mother. McD[illegible] that the less a child can assert himse[illegible] independent play, the greater the freq[illegible] sive clinging and repudiation. The imp[illegible] observations is that significant conflic[illegible] in the mother-child relationship if [illegible] does not support the child's develop[illegible] ward autonomy.

With the development of the capacity [illegible] tational thought" (75) and symboliza[illegible] develops the use of transitional objects [illegible] use his relationship with his father mo[illegible] as a way to mediate the shift from t[illegible] with his mother toward autonomy (28

At about 18 months the infant develo[illegible] both to retain the memory of a concret[illegible] has disappeared ("object permanence" [illegible] the image of the mother in her abse[illegible] memory") (74, 75). Throughout mo[illegible] ment, although the image of the moth[illegible] cur to the child, it does not seem to p[illegible] absence, suggesting an incomplete in[illegible] the mother's caring functions and a[illegible] on her actual presence. Kernberg (7[illegible] that when the child is frustrated by h[illegible] ture, he is overwhelmed with rage an[illegible] image of the loving relationship with h[illegible] To preserve this comforting fantasy [illegible] sociates it and sees himself as a "ba[illegible] doned by an angry mother. The child [illegible] profound separation anxiety in the fo[illegible] ness and a negative sense of self, with [illegible] the "good" images.

The task of the mother during thi[illegible] tolerate sufficiently her own wishes [illegible] and autonomy so that she can respon[illegible] pathic way to corresponding wishes [illegible] out seeing them as "bad" or dangero[illegible] ing with retaliation or withdrawal (4-9 [illegible] associates (76) described two kinds o[illegible] ure. One group of mothers who had d[illegible] ating their own dependency responde[illegible] anger to their child's clinging by say[illegible] minute ago you didn't want me, no[illegible] you." Presumably, this response wou[illegible] in the child about his wishes for nurtu[illegible] group of mothers with conflicts abo[illegible]

sponded to the child's autonomous moves with, "You think you can manage on your own, well go ahead." This response threatens the child with abandonment and inhibits his freedom to explore because of the reactive fantasy: "If I grow up, I'll be all alone."

The implication drawn from these observations is that this kind of chronic withdrawal represents the mother's defensive inability to distinguish between her own unresolved needs (for the child's response to her) and her recognition of the needs of her child for autonomy and support. This defensive response from the mother is contributed to by her own conflicts and by the increased aggressiveness of her 2-year-old during the anal period.

Adler (44) described the "good enough mother" (49) of this subphase as one who is not afraid of her own or her child's anger and can be firm when she needs to frustrate. She has confidence in her basic goodness and a capacity to care without having to retaliate for old hurts. The descriptions of Mahler and associates (27) indicate that there is a broad spectrum of "good enough" mothering responses. Typical failures in the interaction between mother and child, then, are likely to represent chronic empathic insensitivity from mothers at the ends of this spectrum in interaction with particularly sensitive infants.

Toward the end of rapprochement, the child's cognitive apparatus sufficiently matures so that he can notice that the same mother both gratifies and frustrates. Winnicott (24) suggested that if the mother can "contain" the child's aggression (by nonanxious, firm limit setting) while continuing to provide love and understanding, she will demonstrate to him that she is not created or changed by his impulses and that she is separate from him and not a creation of his projections. Such a response allows the child to develop a relationship with her as a real and autonomous person and helps the child to tolerate his anger and put it in perspective by allowing him to recognize that it cannot destroy his loving mother (by turning her into a bad, angry, or anxious mother). In addition, the mother's response will help strengthen the child's conviction in the strength of his good self-image and that of his mother and will decrease the child's fear of his own aggressive tendencies (7).

Alternatively, if the mother, because of unacknowledged conflict revived by the interaction, retaliates for her infant's aggression or withdraws from his demands, she will confirm his fear of aggressive fantasies, making it difficult for him subsequently to integrate them. Responding to the withdrawal, the infant generates increased rage and greater demands (e.g., clinging), which contributes to a spiraling crisis in their interaction and an intensification of the infant's need for defensive splitting and projection, the phenomena characteristic of borderline patients.

With successful negotiation of rapprochement the child develops the capacity for ambivalence and object constancy (27, 74). The ambivalently held image of the mother is more stable in the face of frustration, providing the infant an inner sense of comfort and contributing to his or her capacity to experience guilt, concern, depression, and increasing anxiety tolerance. The infant's image of himself now begins to develop increasing complexity, affects are modulated, ego control of impulses is increased, and there is a clearer sense of self and others. Observers of the child during this subphase (59, 73) have noted that with this development there is a shift from self-centered, demanding, clinging behaviors to more mature expressions of affection, trust, confidence, regard for the interests and feelings of others, cooperation, sharing, making sacrifices, and offering gifts.

Latency

The relative absence of clinical descriptions of borderline phenomena in the literature of the latency period (ages 6–10) suggests a relative decrease in symptomatic behavior during this period. Chiland and Lebovici (77), however, described the two borderline qualities of inhibition and excitability as emerging in some children during latency in response to the disciplinary and learning requirements of school. These children were described as rejecting attempts at communication and refusing to carry out tasks. Despite high learning performance, they were described as exploding periodically in rage. The authors commented on the characteristic contrast between good intellectual development and poor relationship modalities in these children that marked their "developmental disharmony." Again, in these descriptions, the two types of borderline presentation were seen: cold, detached, and removed versus subject to unpredictable outbursts of rage. The authors also commented on the probable use of projective identification by these children, noting that "the interlocutor himself feels the whole burden of anxiety."

Adolescence

Several authors (65, 78, 79) have perceived a recapitulation of the dynamic themes of separation-individuation during the adolescence of the borderline child, a period when borderline symptomatology often becomes apparent. With my colleagues at NIMH (78, 79) I observed a family group regression that occurs during the adolescence of the borderline patient in which family members respond with retaliation or withdrawal to autonomous or dependent behaviors of the adolescent. The conflict between the striving for autonomy and the fulfillment of dependency needs revived in adolescence is inadequately resolved in these families because of a regressive, shared use of projective identification (38) in which the adolescent becomes the bearer of disavowed aspects of the parents. In some families the child's dependent wishes are seen as devouring demands from which the family members withdraw. This withdrawal often represents parental anxiety about their own wishes to be given to, which they cannot acknowledge. In other families, the adolescent's autonomous strivings are interpreted as a

hateful abandonment of the family, which the parents cannot accept. In these families parental strivings for autonomy are disavowed, seen as bad, and projected onto the adolescent, resulting in a defensive inability to respond to the adolescent's autonomous development with the necessary support.

Masterson and Rinsley (65, 80) described the latter group in terms of the adolescent's "abandonment depression," which is defended against by splitting, acting out, and other pathological maneuvers. They viewed as the "basic dynamic theme" of the borderline patient that "the borderline mother withdraws emotional supplies at her child's efforts to separate and individuate." This is a characteristic phenomenon observed by several authors (42, 78). The consequence of this maternal withdrawal in the face of separation is that the child is torn between the engulfment of symbiosis if he moves toward his mother and the experience of loss and abandonment if he moves away. Zinner and my study of the families of these patients in interaction (78) revealed that this retaliatory withdrawal of supplies is a shared family dynamic that is only one element in a family regression involving all family members.

The borderline adolescent's alienation, aggressive responses, and inadequately structured self-image (81) contribute to this family turmoil, but parental contributions are also significant. Our analysis of family interactions (79) revealed that these parents depend heavily on projective identification for their own defensive organization and that in this process there is considerable collusion from the child. We also observed a blurring of parental capacity to experience themselves as separate from the particular child in the areas of conflict and an idiosyncratic but often overlapping content of parental projections involving disavowed wishes for dependency or autonomous strivings (78, 79).

Although Masterson (82) found the parents of the borderline patient to be borderline themselves, this finding does not agree with our observations of significant variability in parental psychopathology (79) or with the observations of Margaret Singer (8), who found that 84% of borderline patients had normal or neurotic parents according to psychological tests. Although some authors (6, 65)[1] have discussed these parents in descriptive terms (i.e., "ineffectual, passive father," "intrusive, dependent mother"), other authors (78, 79, 83) have described a more dynamic, shifting tension between parent and child.

The latter observers illustrated how family members' use of primitive defenses may be encapsulated in response to issues involving certain offspring. In interaction with siblings or the outside world, they may use more advanced ego defenses and greater maturity but may regress to fixation points relating to deficient resolution of symbiosis and identity formation in relation to the designated borderline child. Singer and Wynne (83) commented on the discrepancy between the severity of the disturbance when family members interact compared with the relatively mild distu[illegible] family member shows individually. They [illegible] that in attempting to understand the famil[illegible] it is insufficient to look only at the indivi[illegible] relation to the individual child. Their [illegible] (78, 79, 83) indicate that there are contri[illegible] the entire family group that affect the nat[illegible] velopmental interference.

DISCUSSION

The continuing study of the psychopat[illegible] borderline patient has inevitably led to [illegible] interest in and examination of a two-per[illegible] gy. The remnants of early symbiotic int[illegible] in the interpersonal use of projective id[illegible] the borderline patient are evident in the [illegible] pist interaction, the mother-child respo[illegible] family life of the borderline adolescent. [illegible] the complex fantasy life of the neurotic [illegible] his more differentiated and articulated p[illegible] intrapsychic conflict (usually involving [illegible] tasies), the borderline patient presents [illegible] typed, primitive difficulties, frequently [illegible] nonverbally. Often the key to a comp[illegible] these difficulties lies in the affects and [illegible] tasies of the caretaker (e.g., therapist o[illegible]

The growing experience in intensive w[illegible] patients has led to a closer study [illegible] transference phenomena (7, 30), the setti[illegible] work" of the therapeutic interaction (2[illegible] ture of the "holding environment" (10, [illegible] components and complexities of empat[illegible] ures (10, 24, 36–40, 44, 48, 57, 62, 71, 7[illegible] conscious communicative process invo[illegible] interaction (78, 79, 83). In addition, the [illegible] chological defense has been reevaluate[illegible]

Although Klein (34, 35) focused her st[illegible] tive identification on the nature of the [illegible] fantasies, more recent work has focused [illegible] orative nature of this defense (38, 39, [illegible] 85). Much of this work supports the 'de[illegible] an entire range of interpersonal defense[illegible] collaboration of a particular other is nec[illegible] tain defensive equilibrium.

Certainly, unconscious conflict in t[illegible] ternalized in her relationship with the [illegible] to be related in some way to difficulties [illegible] of "adequate symbiosis" as well as in [illegible] choreographed movements required fo[illegible] ration-individuation. Unconscious fant[illegible] fensive collaborative use of particular fa[illegible] to represent disavowed aspects of inne[illegible] family of the borderline adolescent seem[illegible] icant impediment to development. It [illegible] seen how these family interactions affec[illegible] mental matrix in which the infant's ear[illegible] self develops. This question remains a re[illegible] plored frontier of developmental theory

Although there remains significant controversy about the applicability of child observation to adult phenomena as well as serious debate about the possibility of recreating elements of the relationship between infant and mother in the therapeutic situation (86), conceptual attempts to make these comparisons have produced fascinating new insights. The delineation of the therapist's "holding" function, of his task of "containing" the patient's affects and projections, and of the hazard of his own projections interfering with the therapeutic process (46, 84, 85) have all emerged in part from this study of the borderline patient and his development. All seem in some way to have relevance to the developing understanding of the complex preverbal interaction between infantile impulses and human environmental responses from which personality evolves.

The increasing overlap of the observations, formulations, and inferences derived from the three different areas of study reviewed above suggests at least an approximation to reality that future follow-up studies should address. The data from the current studies have already made an important contribution to the therapist's ability to listen better to particular elements of these patient's productions, to develop more accurate empathic responses, and to provide borderline patients with some coherent organization for their chaotic experience.

Bilateral and Unilateral ECT: Effects on Verbal and Nonverbal Memory

BY LARRY R. SQUIRE, PH.D., AND PAMELA C. SLATER

The memory loss associated with bilateral and nondominant unilateral ECT was assessed with verbal memory tests known to be sensitive to left temporal lobe dysfunction and with nonverbal memory tests known to be sensitive to right temporal lobe dysfunction. Bilateral ECT markedly impaired delayed retention of verbal and nonverbal material. Right unilateral ECT impaired delayed retention of nonverbal material without measurably affecting retention of verbal material. Nonverbal memory was affected less by right unilateral ECT than by bilateral ECT. These findings, taken together with a consideration of the clinical efficacy of the two types of treatment, make what appears to be a conclusive case for unilateral over bilateral ECT.

ELECTROCONVULSIVE THERAPY (ECT) has long been considered an effective treatment for depressive illness (1, 2). The memory loss associated with this treatment has been well documented (3–5). For example, following conventional bilateral treatment, memory loss can extend to events that occurred many years before treatment as well as to events that occur during the weeks after treatment. Memory functions gradually improve as time passes after treatment (6).

It has been generally accepted that right unilateral ECT is a clinically effective treatment that produces less impairment of new learning capacity and less amnesia for remote events than bilateral ECT (7–13). However, since right unilateral ECT is specifically associated with impairment in nonverbal memory (e.g., memory for spatial relationships, faces, designs, and other material that is difficult to encode verbally (14–17), and since most studies of ECT and memory loss have employed verbal memory tests, the actual extent of memory loss associated with right unilateral ECT has remained somewhat unclear. It has been suggested that the amnesic effects of left or right unilateral ECT may be similar to the effects of left or right temporal lobe dysfunction (18). Accordingly, if memory were assessed with nonverbal tests specifically sensitive to right temporal lobe dysfunction, the amnesic effect of right unilateral ECT might prove to be as great as or even greater than that of bilateral ECT.

Only two studies have addressed this issue directly, employing verbal and nonverbal memory tests with patients receiving bilateral or right unilateral ECT. In the first study (15) impairment in one nonverbal test was somewhat greater after bilateral ECT than after unilateral ECT, but this difference was not statistically significant. In the second study (16) the results were ambiguous. Impairment in a nonverbal test was greater in the unilateral group after 4 treatments, but greater in the bilateral group 3 months after treatment. That study was further complicated by the fact that one-third of the patients given unilateral treatment did not have a grand mal seizure. Finally, since it was not clear how patients with identified right unilateral lesions would perform on the nonverbal tests used in these two studies, it was difficult to be sure how specifically sensitive the tests were to right hemispheric dysfunction.

The present study investigated memory functions in patients receiving bilateral or right unilateral ECT. Assessments of memory were made with two verbal tests known to be sensitive to left temporal lobe dysfunctions and two nonverbal tests known to be sensitive to right temporal lobe dysfunction.

METHOD

Subjects

The subjects were 72 psychiatric inpatients (53 women and 19 men), from 4 private hospitals, who had been prescribed a course of ECT. The diagnoses as recorded upon admission by the psychiatrists were depression (N=55; this diagnosis included designations of primary affective disorder, involutional melancholia, manic-depressive, and psychotic depression),

Some of the data reported here were included in a review of ECT and memory loss presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

The authors are with the University of California, San Diego, where Dr. Squire is Associate Professor of Psychiatry, School of Medicine, and Ms. Slater is Research Assistant. Address reprint requests to Dr. Squire at the Veterans Administration Hospital, San Diego, Calif. 92161.

This work was supported by Alcohol, Drug Abuse, and Mental Health Administration grant MH-24600 from the National Institute of Mental Health and by the Medical Research Service of the Veterans Administration.

The authors wish to thank Mesa Visa, San Luis Rey, Centre City, and Mercy Hospitals for their full cooperation, and Neal Cohen for his helpful discussion.

neurotic depression (N=11), schizo-affective disorder (N=5), and hysterical personality (N=1). Patients with neurological disorders, schizophrenia with depression, depression secondary to alcoholism or drug abuse, and patients who had received ECT during the previous 12 months were excluded from the study. Most of the patients (N=45) had not received ECT before; 27 had received ECT 1 to 15 years earlier.

The 72 patients in the study were assigned to 3 groups (table 1). Group 1 consisted of 33 patients who had been prescribed bilateral ECT. Group 2 consisted of 21 patients who had been prescribed right unilateral ECT. The choice of bilateral or unilateral ECT depended on the preferences of the individual psychiatrists and was therefore not random. However, since the patients about to receive bilateral or unilateral treatment did not differ measurably on their memory test scores before ECT (figure 1), it seems reasonable to assume that group differences emerging after ECT can be attributed to the type of ECT administered. Group 3, a control group, consisted of 18 randomly selected patients who were only tested before receiving a course of ECT. Fourteen of these patients were scheduled to receive bilateral ECT and 4 right unilateral ECT. All subjects were determined to be strongly right-handed; they reported that they did not use their left hand for any everyday activity and had no left-handed parent or sibling.

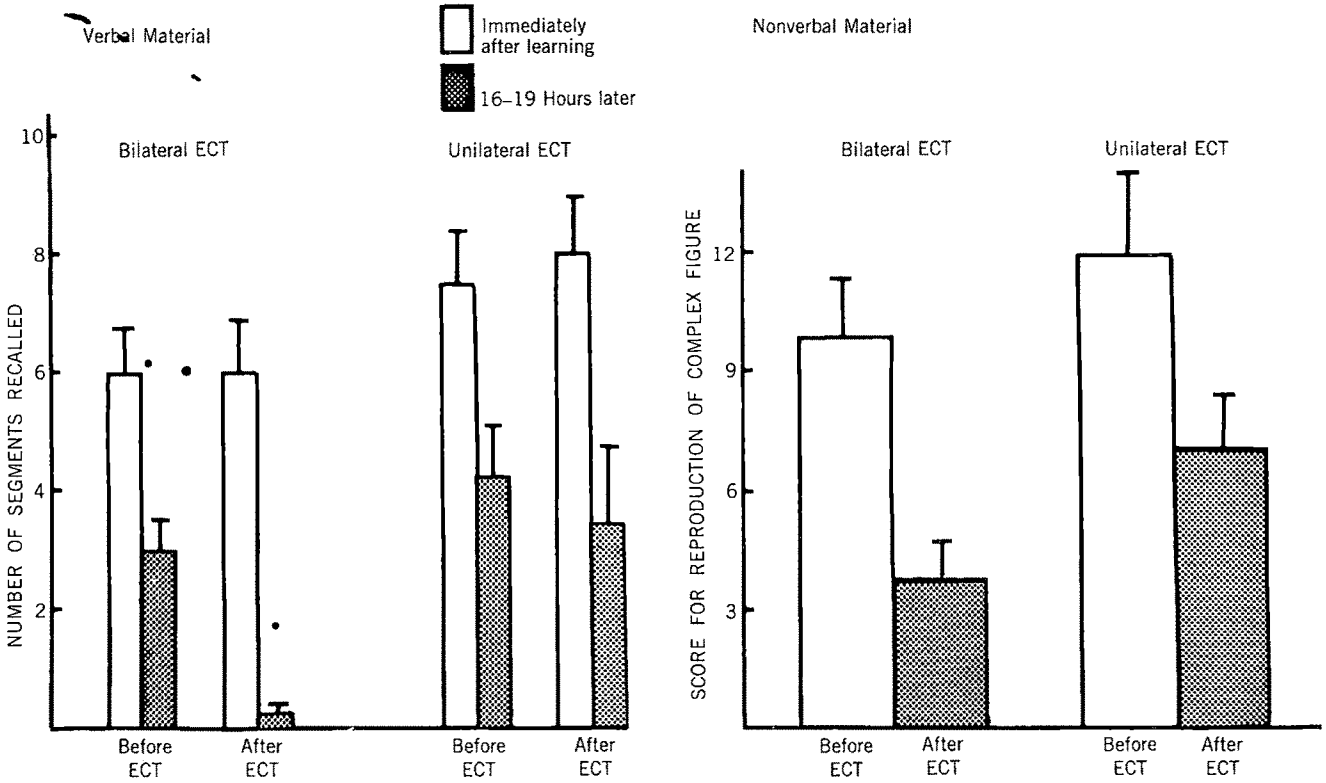
ECT

ECT was administered three times a week on alternate days following medication with atropine, methohexital sodium, and succinylcholine. Bilateral and unilateral treatments were administered using a Medcraft B-24 machine. For bilateral treatment electrode placement was temporal-parietal; for unilateral treatment both electrodes were placed on the right side of the head, as described by McAndrew and associates (19) (N=19) and by D'Elia (7) (N=10). Amnesic effects of nondominant unilateral ECT have been reported to be similar despite wide variation in electrode placement (20, 21). The stimulus parameters (140–170 v for .75–1.0 seconds) were sufficient to induce a grand mal seizure throughout the course of all treatments.

Tests and Procedures

Two memory tests, each consisting of a verbal and a nonverbal portion, were employed.



Test 1A (verbal portion: story recall). A short paragraph was read to the subject (6). Patients with identified dysfunction of the left temporal lobe are known to perform more poorly on this test than patients with dysfunction of the frontal parietal or right temporal region (22). Immediately after hearing the story, and again the next day (16–19 hours later), subjects were asked to recall as much as they could remember of it. The paragraph was divided into 20 segments, and the score was the number of segments recalled. Eighteen patients receiving bilateral ECT and 13 receiving right unilateral ECT were tested before treatment and again, with an equivalent form of the te after the fifth treatment of the series.

Test 1B (nonverbal portion: memo figure). Subjects copied a complex geo (the Rey-Osterrieth figure [23] or the [24]) and were then asked to reproduce ry 16–19 hours later. Patients with righ sions are known to be deficient on this patients with left temporal lesions exhi ment (25). The score for this test de number of properly placed line segmen score=36 points). The same patients (above) were tested with one of these ECT and with the other one 6–10 hour treatment.

Test 2A (verbal portion: short-te tractor test). Subjects were shown a gram, distracted for a variable interva seconds), and then asked to recall the c Patients with left temporal lesions are i task; patients with right temporal lesions Subjects received 8 trials at each rate and their score was the number of co rectly recalled without regard to order. score was 24. Fifteen patients receiving were tested on two occasions with equi this test. These sessions were schedule ter the first treatment and 2–3 hours treatment of the series. In addition, 8 p ing right unilateral ECT were tested 2- their first and third treatments. Fina were tested on one occasion 1–2 days b treatment.

Test 2B (nonverbal portion: spatial jects attempted to remember the posi circle located along an 8-inch horizonta with right temporal lesions are impair patients with left temporal lesions are jects inspected the circle on the line for then were distracted for 6, 12, or 24 seco ing strings of random digits into numeric subjects attempted to mark on a differe the remembered position of the circle

FIGURE 1
Retention of Test 1 Verbal and Nonverbal Material by Patients Receiving Bilateral ECT (N=18) and Right Unilateral ECT (N=13)

trials were given, with 8 at each of the three retention intervals. The score on each trial was the distance (in millimeters) between the position of the originally presented circle and the position of the circle as marked by the subject. The score on the test at each retention interval was the total error (in millimeters) for all 8 trials. Test 2B was given on the same occasions and to the same patients as test 2A (above).

RESULTS

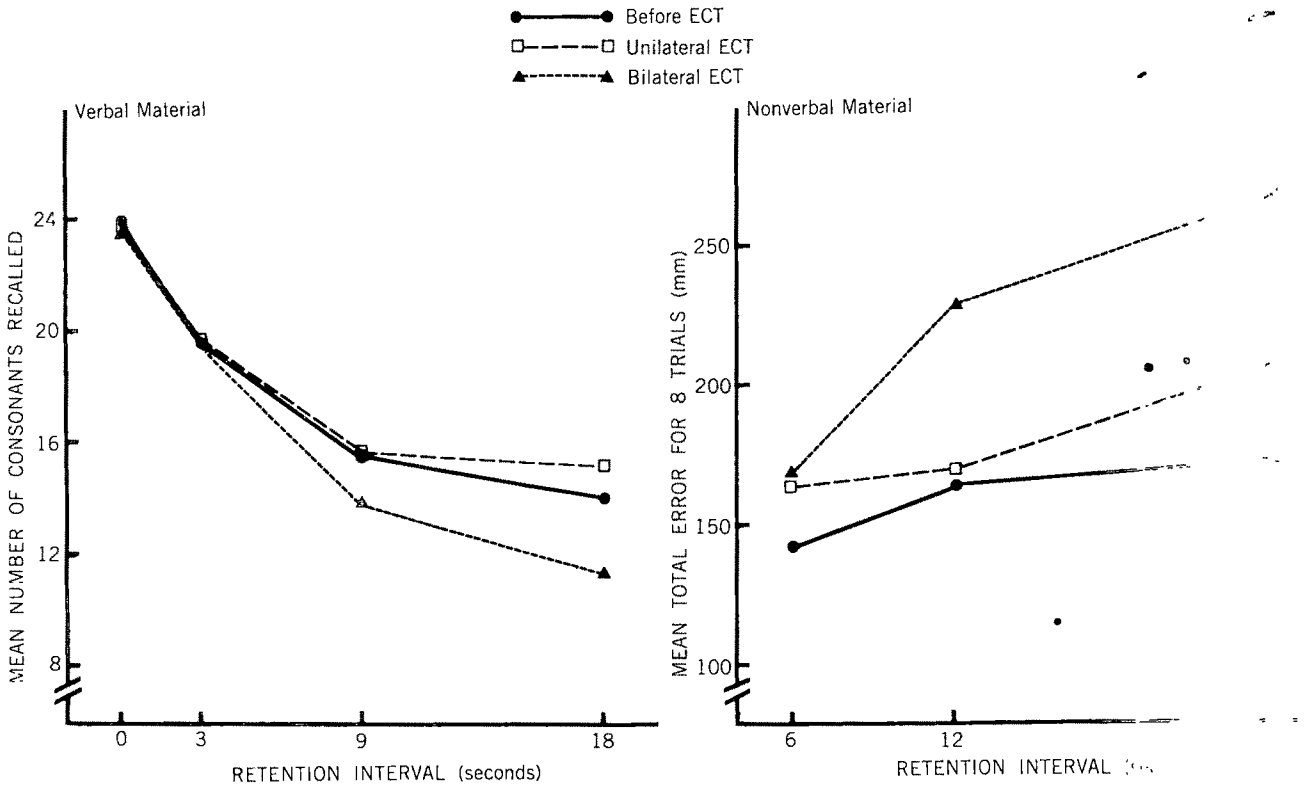


Figure 1 shows the results with test 1 for patients who received bilateral or unilateral ECT. Before ECT these two groups of patients did not differ from each other on any of the measures of immediate or delayed recall (for the verbal test, $t<1.5$, $p>.10$; for the nonverbal test, $t=0.7$, $p>.10$). After ECT patients receiving bilateral treatment were able to remember verbal material immediately after hearing it as well as they could before ECT (before ECT versus after ECT, $t=0.1$, $p>.10$), and they were able to copy a complex figure as well as before ECT ($t=0.1$, $p>.10$). However, their performance was severely impaired on delayed tests of verbal and nonverbal memory (verbal test: before ECT versus after ECT, $t=5.6$, $p<.01$; nonverbal test: before ECT versus after ECT, $t=3.7$, $p<.01$).

Right unilateral ECT did not affect verbal memory, as measured by test 1A. That is, the delayed recall scores of patients receiving right unilateral treatment were about the same after ECT as before ($t=0.6$, $p>.10$). However, nonverbal memory was significantly impaired by right unilateral ECT (test 1B). Before unilateral ECT the score for reproducing the geometric figure after a delay was 11.9, and after unilateral ECT the corresponding score was 7.1 ($t=2.7$, $p<.05$). This impairment in nonverbal memory associated with unilateral ECT was not as great as the impairment in nonverbal memory associated with bilateral ECT ($t=2.1$, $p<.05$).

Figure 2 shows the results with test 2 for patients receiving bilateral ECT, patients receiving right unilateral ECT, and a control group of patients about to begin a course of bilateral or unilateral ECT. For the short-term memory distractor test, patients receiving bilateral ECT were impaired, but patients receiving right unilateral ECT performed normally. An analysis of variance with repeated measures on one factor (28) indicated that the scores of bilateral patients were significantly lower than those of both unilateral patients ($F=10.8$, $p<.01$) and control patients ($F=5.7$, $p<.01$). The scores of unilateral patients and control patients were not measurably different ($F=0.8$, $p>.10$).

For the spatial memory test bilateral ECT also produced a marked impairment (bilateral group versus control group, $F=22.4$, $p<.01$). The scores of unilateral patients were also poorer than those of control patients, although this difference fell short of significance

FIGURE 2
Recall of Test 2 Verbal and Nonverbal Material by Patients Receiving Bilateral ECT (N=15), Right Unilateral ECT (N=8), and by Control Subjects About to Begin a Scheduled Course of ECT (N=18)

(F=2.64, p=.12). Finally, the effect on nonverbal memory associated with unilateral ECT was not as great as the effect associated with bilateral ECT (F=9.6, p<.01).

DISCUSSION

The results can be summarized by three main conclusions.

1. Bilateral ECT markedly impaired the ability to retain both verbal and nonverbal material.
2. Right unilateral ECT impaired the ability to retain nonverbal material without measurably affecting memory for verbal material.
3. The impairment in nonverbal memory associated with right unilateral ECT was less than the impairment in nonverbal memory associated with bilateral ECT.

The findings that bilateral ECT markedly affected memory and that right unilateral ECT exerted a material-specific effect on nonverbal memory are consistent with the results of a number of studies of ECT and memory loss (3–5, 7). However, it should be noted that the extent to which bilateral or right unilateral ECT impairs memory depends on the sensitivity of memory tests to the effects of ECT. For example, in the present study right unilateral ECT had no measurable effect on verbal memory; yet performance on some verbal memory tests can be impaired by right u[illegible] ment (10, 12). Accordingly, it is diffic[illegible] the amnesic effects of bilateral and ri[illegible] ECT unless these effects are assesse[illegible] study using the same tests.

The present study employed memory te[illegible] be sensitive to either left or right temp[illegible] function. The results clearly indicated tha[illegible] right unilateral ECT on both verbal a[illegible] memory was less than that of bilateral[illegible] sometimes been assumed that right u[illegible] produces as much memory dysfunction[illegible] ECT on those aspects of memory functi[illegible] with the right hemisphere. To our kno[illegible] study reported here is the first to clea[illegible] strate that right unilateral ECT produc[illegible] ory dysfunction for nonverbal materia[illegible] ECT.

The therapeutic efficacy of bilateral [illegible] ECT has been compared in a large num[illegible] (for reviews see references 29 and 30). T[illegible] these studies indicate that courses of b[illegible] lateral ECT are approximately equivale[illegible] to similar reductions in depressive sym[illegible] sociated with similar relapse rates, and [illegible] efficacy at follow-up. One review (29) [illegible] that the slight disadvantage in immed[illegible] sometimes reported for unilateral treatme[illegible]

the apparently widespread impression[1] that unilateral ECT is not as effective as bilateral ECT, may be due to occasional failures to produce a maximal seizure with the unilateral technique. Since the therapeutic effect of ECT is bound to the seizure (32), even one submaximal seizure during a course of unilateral treatment could account for reported slight differences between unilateral and bilateral ECT. Several practical suggestions to ensure that unilateral ECT produces a grand mal seizure have been outlined (29).

When given properly, unilateral ECT seems to be clearly preferable to bilateral ECT since the risks to verbal and nonverbal memory are less than for bilateral treatment. It should be noted that some risks to memory exist even for unilateral ECT. The benefits to be derived from this procedure should therefore be weighed carefully against these risks and against the possible risks of alternative therapies to form a basis for clinical judgment.

Withdrawal Syndromes Associated with Antipsychotic Drugs

BY GEORGE GARDOS, M.D., JONATHAN O. COLE, M.D., AND DANIEL TARSY, M.D.

Withdrawal symptoms frequently follow abrupt discontinuation of antipsychotic compounds. In addition to other somatic symptoms, withdrawal-emergent dyskinesias may be observed. "Covert dyskinesia" refers to a masked form of tardive dyskinesia that becomes clinically detectable only after antipsychotic drugs are withdrawn or their dosage is reduced. Withdrawal dyskinesia appears under similar circumstances but disappears spontaneously in 6 to 12 weeks. Cholinergic overactivity and changes in dopamine-acetylcholine balance in the basal ganglia may underlie these withdrawal syndromes. The principal value of the concept of covert dyskinesia is in the secondary and tertiary prevention of tardive dyskinesia through early discovery and treatment.

THE EFFECTS of withdrawal of antipsychotic drugs have not been adequately studied. In usual clinical practice, antipsychotics are withdrawn abruptly with no expectation of untoward effects other than the possibility of psychotic relapse. There are at least two compelling reasons to focus attention on the sequelae of drug discontinuation. Withdrawal symptoms that develop may in some cases mimic symptoms of psychotic exacerbation and therefore may result in unwarranted resumption of drug therapy. In addition, dyskinesias may be seen following antipsychotic drug withdrawal, including a form of tardive dyskinesia that is suppressed during drug administration. The dose-related suppression of dyskinetic movements by dopamine-blocking antipsychotic drugs is probably the major reason for the widely differing prevalence rates of tardive dyskinesia (ranging from .5% to 40%, according to Crane [1]) reported in the literature. Withdrawal-emergent dyskinesia, like withdrawal symptoms, may be confused with signs of psychotic relapse (2); hence the careful assessment of pa[illegible] postwithdrawal weeks is more than an exercise.

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Gardos is Director, Institute for Research and Rehabilitation, Boston State Hospital, 591 Morton St., Boston, Mass. 02124. Dr. Cole is Head, Psychopharmacology Unit, McLean Hospital, Belmont, Mass. Dr. Tarsy is Staff Neurologist, Veterans Administration Hospital, Boston, Mass.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant MH-27505 from the National Institute of Mental Health.

AUTONOMIC AND BEHAVIORAL SYM[illegible] WITHDRAWAL

During the first week or two followi[illegible] antipsychotic drugs, a number of soma[illegible] may occur. These symptoms, aptly labe[illegible] effects" by Lacoursiere and associates [illegible] consist of one or more of the following: [illegible] ing, diarrhea, perspiration, restlessness, [illegible] norrhea, headaches, increased appeti[illegible] ness. Although some drug studies have [illegible] withdrawal symptoms (4–6), it seems [illegible] that such symptoms were not looked [illegible] sequently may have been missed. In [illegible] where careful observations were made [illegible] incidence of withdrawal symptoms rang[illegible] to 75%.

Symptoms typically begin during the [illegible] after drug discontinuation, peak during th[illegible] and disappear by the end of the second [illegible] affected patients have only one or two [illegible] which are usually mild enough to be elic[illegible] direct questioning. Symptoms usually fa[illegible] occasional severe cases may require tem[illegible] ment with antihistamines or sedatives. [illegible] withdrawal appears more likely to induce [illegible] symptoms than gradual withdrawal (9). [illegible] relationship has been demonstrated [illegible] withdrawal dosage and the incidence o[illegible] symptoms (3, 7, 13). In one study (11) a [illegible] greater proportion of women than men ga[illegible] syndrome.

Antipsychotic drugs all possess centra[illegible] eral antimuscarinic properties to varying [illegible] 15). It is tempting to postulate that at lea[illegible] drawal symptoms may be due to a choline[illegible] occurring when antipsychotic drugs are [illegible] The following observations support this [illegible] with marked anticholinergic properties, [illegible] promazine and thioridazine, are assoc[illegible] highest rates of withdrawal symptoms (3[illegible] same may be true for clozapine, a very [illegible] cholinergic new antipsychotic agent (16[illegible] drawal of piperazine phenothiazines, whi[illegible] weaker anticholinergic agents (14), rare[illegible]

symptoms unless antiparkinsonian drugs are simultaneously withdrawn (3, 17, 18). Imipramine, an antidepressant with marked anticholinergic effects, also yields a high incidence of withdrawal symptoms (19). Finally, most of the common withdrawal symptoms, e.g., nausea, vomiting, and sweating, can be produced by the acute administration of physostigmine, a drug with marked central and peripheral cholinergic actions (20, 21); these same symptoms can be abolished by anticholinergic agents (20).

EXTRAPYRAMIDAL COMPLICATIONS OF WITHDRAWAL

Parkinsonism

Drug-induced parkinsonism tends to improve following drug withdrawal (22). However, cases often persist for at least 4 months (23, 24), and, in rare cases, subtle signs have persisted for as long as 9–18 months (25). When antiparkinsonian drugs are withdrawn at the same time as antipsychotics, parkinsonian symptoms of rigidity, tremor, and akinesia may recur (17, 18), usually peaking at about 4 days after drug withdrawal, with gradual fading thereafter. Simpson and associates (17) have suggested that the temporary exacerbation of parkinsonism is the result of unopposed dopamine blocking effects of the more slowly excreted phenothiazines in the absence of protection by the more rapidly excreted antiparkinsonian drug.

Withdrawal Dyskinesia

A syndrome resembling tardive dyskinesia may appear for the first time following antipsychotic drug discontinuation but, in contrast to tardive dyskinesia and like other withdrawal symptoms, is self-limited. Case reports have described dyskinesias occurring after withdrawal of chlorpromazine and fluphenazine (26), mesoridazine (27), and haloperidol (28, 29). In the above cases, dyskinetic symptoms uniformly appeared within a few days after drug withdrawal and lasted for 1–22 weeks. Degkwitz and associates (11) observed 9 cases of withdrawal dyskinesia among 53 patients withdrawn from antipsychotics. In the 6 male patients dyskinesia disappeared in 4–7 weeks; in the 3 female patients dyskinesia occurred later and lasted somewhat longer (8–13 weeks).

Withdrawal-emergent dyskinesia has also been reported in children (30). Fourteen of 34 schizophrenic children aged 6–12 developed choreiform dyskinesia and ataxia, primarily affecting the extremities, trunk, and head, when withdrawn from antipsychotics. In half of the children the dyskinesias disappeared spontaneously within 5 weeks; in the other half the dyskinesias were suppressed by the reintroduction of antipsychotic drugs.

Similar to prevailing concepts of the pathophysiology of tardive dyskinesia, withdrawal dyskinesia is thought to be due to a temporary hyperdopaminergic state in the basal ganglia following the discontinuation of dopamine-blocking antipsychotic drugs. Experimentally induced supersensitivity to dopamine in rats dissipates within a few weeks (31) and, therefore, may be regarded as a useful animal model for withdrawal dyskinesia.

Covert Dyskinesia

According to a review by Crane (1), 5% to 40% of neurologically asymptomatic patients develop dyskinesia upon discontinuation of antipsychotic drugs. Because of the relatively short period of observation of these patients, it is unclear whether such dyskinesias are more commonly transient or persistent. The term "covert dyskinesia" refers to a dyskinesia that is not detectable during drug administration but develops in response to dose reduction or drug discontinuation, does not disappear spontaneously, and may in fact become permanent.

Degkwitz and associates (11) found that 6 of 53 patients withdrawn from antipsychotics developed dyskinesia that persisted over the 14-week study period. In another study by the same group (12), 30 of 130 patients developed dyskinesia after drug withdrawal although, since the length of postwithdrawal observation was not specified, some of these patients may have manifested transient withdrawal dyskinesias. One continuing study has found that 20% (9 of 43) of a group of young patients (mean age=25 years) developed distinct orofacial and other types of dyskinesias on antipsychotic drug withdrawal.[1] Extremity movements tended to dominate the clinical picture, as they do the withdrawal-emergent dyskinesia of children.

Hoff and Hoffman (32) found a 10% incidence of withdrawal dyskinesia in 190 patients withdrawn from antipsychotics. In the studies by Small and Hoff and Hoffman, patients were returned to drugs because of increased symptoms; thus it was not possible to differentiate withdrawal from covert dyskinesias. Hershon and associates (24) withdrew trifluoperazine in 23 patients. Five new cases of dyskinesia, characterized most frequently by motor restlessness of the trunk and extremities, emerged and persisted for 16 weeks. Crane (33) also described a case in which massive dyskinesia with diffuse restlessness dominated the picture 3 weeks after antipsychotic drug withdrawal. Other reports (29, 34) provide additional documentation of cases of covert dyskinesia in which dyskinesia appearing after drug withdrawal tended to persist for many months.

RELAPSE INTO PSYCHOSIS

Withdrawal of antipsychotic medication is frequently followed by the reappearance of schizophrenic symptoms. The time at which relapse occurs is highly variable (2). Donlon and Blacker (35) described four distinct stages during decompensation: denial and anx-

iety, depression and intensification of defense mechanisms, internal chaos, and subjective relief. Some of the early symptoms of relapse such as anxiety, tension, and insomnia overlap withdrawal symptoms, and in some patients differentiating these two syndromes may not be easy. The withdrawal syndromes described above are summarized in table 1.

TARDIVE, WITHDRAWAL, AND COVERT DYSKINESIA

It may be argued that no convincing evidence indicates that covert dyskinesia is distinct from tardive dyskinesia. The introduction of "covert dyskinesia" as a diagnostic entity might, therefore, confuse rather than clarify clinical thinking. There are other problems with the concept of "covert dyskinesia." By definition, the diagnosis can only be made after lengthy drug withdrawal during which withdrawal-emergent dyskinesia fails to disappear. Obviously a lengthy period of drug withdrawal is an impractical diagnostic procedure because of the risk of psychotic relapse (36). A further objection is that many patients with "covert dyskinesia" might in fact show subtle early signs of dyskinesia if they were thoroughly examined while still on drugs, and therefore should be considered as examples of undiagnosed tardive dyskinesia.

Our view regarding the interrelationships of the three clinical types of dyskinesia may explain the emphasis accorded to covert dyskinesia. We suggest that late appearing antipsychotic drug-induced dyskinesias form a continuum from mild, completely reversible cases ("withdrawal dyskinesias") to ob... sistent, and sometimes irreversible tar... nesias. We also assume that with advanc... continued drug treatment patients may pr... this continuum, although specific examples ... this assumption have not yet been reporte... ous that some patients may fall between t... tremes. Whether such patients are given ... "atypical dyskinesia" (37), withdrawal dy... covert dyskinesia may be academic.

Recognition of covert dyskinesia is difficult ... it must be distinguished from withdrawal ... doses of antipsychotics may be developing the neuropathological substrate for tardive dyskinesia, although overt movements are suppressed by the drug. We hope that such concern will lead to attempts to reduce dosage whenever feasible (2). The awareness of covert dyskinesia may also induce clinicians to be vigilant for very early signs of overt dyskinesia. Acceptance of the notion that a proportion of drug-treated patients harbors an early hidden form of tardive dyskinesia may stimulate efforts to develop diagnostic tests to uncover such patients. One promising approach is the exploration of administration of challenge doses of central anticholinergic and dopaminergic substances to patients receiving maintenance antipsychotics. L-Dopa (38) and benztropine (39) given intravenously have been tried for this purpose. The assumption is that those patients in whom dyskinesia is unmasked by exposure to dopaminergic or anticholinergic drugs might be suspected to harbor covert dyskinesia.

Tricyclic Antidepressants: Plasma Levels and Clinical Findings in Overdose

BY DAVID N. BAILEY, M.D., CRAIG VAN DYKE, M.D., RENE A. LANGOU, M.D., AND PETER I. JATLOW, M.D.

Following amitriptyline or imipramine overdose by 30 patients, total plasma concentrations ranged from 29 to 1732 ng/ml but did not correlate well with physical findings or most electrocardiographic changes. Only those patients with a QRS interval greater than 0.1 second had significantly elevated plasma levels. However, a plasma level ratio of the parent drug (amitriptyline, imipramine) to its respective N-desmethyl metabolite (nortriptyline, desmethylimipramine) greater than or equal to 2.0 was associated with an acute overdose. This ratio was more useful than total plasma levels in differentiating an overdose from a therapeutic dose with associated toxicity and an elevated steady-state plasma level.

ONE OF THE major risks in treating depressed patients with tricyclic antidepressants is that of administering a class of cardiotoxic and neurotoxic compounds to those patients who are most likely to attempt suicide. Electrocardiographic abnormalities, coma, convulsions, and death have all been reported following tricyclic overdose (1-7). Despite the seriousness and frequency of tricyclic overdose, little information is available to the clinician for making critical decisions concerning the patient's care. How serious is the overdose (or is it an overdose)? Does the overdose warrant hospitalization on a medical ward, and if it does, how long should the cardiac rhythm be monitored, and when can discharge safely occur? Byck (8) has suggested that all patients who have ingested an overdose of tricyclics have their cardiac rhythm monitored for 72 hours. However, a few deaths from sudden arrhythmias have been reported as long as 6 [illegible] ingestion (1, 2, 9).

Since there are few firm guidelines to [illegible] swers to the clinical questions usually [illegible] teraction between the internist and the [illegible] and their perspectives often differ. The [illegible] not want to hospitalize the patient on a [illegible] if the patient must be admitted because [illegible] diac arrhythmias, the internist is eager to [illegible] to a psychiatric ward. The psychiatrist, [illegible] hand, prefers to admit the patient to a [illegible] til it is clear that there will be no sudden [illegible] plications from the overdose.

The development of sensitive and spec[illegible] the accurate measurement of tricyclics [illegible] 13) may provide an additional parame[illegible] this problem. In two different publicatio[illegible] associates (6, 14) presented data on tric[illegible] trations following self-poisonings. How[illegible] and economical reasons have general[illegible] analysis of plasma tricyclic levels to a [illegible] laboratories. With the recent applicatio[illegible] sensitive detectors, which permit the acc[illegible] atively inexpensive measurement of pla[illegible] levels, such analyses may become more [illegible] able to clinicians.

We present the results of a retrospectiv[illegible] cases of overdose with amitriptyline (1[illegible] imipramine (11 cases), the most widely [illegible] cyclics. Plasma concentrations of the p[illegible] (amitriptyline, imipramine) and their res[illegible] macologically active *N*-desmethyl meta[illegible] triptyline, desmethylimipramine) were [illegible] by gas-liquid chromatography using a nitr[illegible] detector (11, 12). Plasma levels were co[illegible] the physical findings in each case and wit[illegible] sion ECGs in 21 cases.

METHOD

The clinical history for all 30 cases was [illegible] rospectively by review of the medical an[illegible] records. Patients who had ingested signifi[illegible] of drugs other than tricyclics were exclu[illegible] study. Initial plasma samples were obta[illegible]

puncture within 2–4 hours following the patient's admission to the medical ward, and later samples were sometimes available for analysis.[1] Twenty-one patients had ECGs performed within 4–6 hours of admission, and 14 of these also had at least one subsequent ECG. The ECGs were reviewed by a cardiologist (R.A.L.) without knowledge of either the clinical history or the tricyclic plasma levels. The electrocardiographic criteria of the Minnesota Code (15) were used in the evaluation of the ECGs: class IV, for the ST segment; class V, for T waves; class VI, for A-V conduction; class VII, for ventricular conduction; and class VIII, for arrhythmias. We considered the QRS duration to be prolonged if it exceeded 0.1 second and the QT interval to be prolonged if it exceeded that predicted for the particular heart rate and sex of the patient by the Ashman, Hull, and Lepeschkin formula (16). Plasma levels of tricyclics were compared with both the physical findings and the ECG data. Levels of significance were determined using Student's t test and the Pearson product-moment correlation method. We considered $p<.05$ as significant.

RESULTS

Nineteen of the 30 cases involved amitriptyline, and 11 involved imipramine. The ingestions frequently included other drugs as well; only 7 patients had taken amitriptyline alone and 6 imipramine alone. However, there was not a significant difference between the mean plasma level of patients taking a pure overdose and those taking a mixed overdose. All but 7 patients had psychiatric histories, and 18 had been receiving tricyclics on a long-term basis. The patients ranged from 13 to 73 years of age; 6 were teenagers, and 24 were women. Although total plasma tricyclic levels did not correlate with age or differ with sex, the levels did correlate weakly with the estimated dose ($r=.40$, $p<.05$).

On admission, the patients' plasma levels of amitriptyline ranged from 29 to 1080 ng/ml, nortriptyline from 0 to 337 ng/ml, and the total level (the sum of the parent drug and the active metabolite) from 29 to 1260 ng/ml. Similarly, plasma imipramine concentrations ranged from 92 to 1515 ng/ml, desmethylimipramine from 31 to 350 ng/ml, and the total level from 123 to 1732 ng/ml. The ratio of the concentration of parent drug to that of the active *N*-desmethyl metabolite (P/M) ranged up to 14.4 (mean±SE=5.4±1.0) for amitriptyline and to 12.9 (3.4±1.1) for imipramine. For the entire series, 19 patients had P/M ratios greater than or equal to 2.0, and an additional 2 patients had no detectable metabolite at the time of drug analysis. Nine of the patients with a P/M ratio greater than or equal to 2.0 had plasma concentrations approaching those reported after therapeutic doses. In 8 patients with more than one determination, the P/M ratio decreased with time.[2]

The most common physical findings were tachycardia (pulse rate >110/minute), 70%; coma (grade 2 or 3[3]), 53%; and pupillary dilatation (estimated subjectively on admission but not quantified), 40%. Hyperreflexia and hypotension, although noted in some patients, were less frequent. Pupillary dilatation occurred more often with amitriptyline overdose (53%) than with imipramine (18%). Hypotension was more frequent with imipramine overdose (63%) than with amitriptyline (16%). We compared the mean total tricyclic levels for all patients with a given physical finding with the mean levels of those patients without the finding. The differences in means for all findings were not significant.

All patients had depressed levels of consciousness when first seen; 14 were grade 1, and 16 were grade 2 or 3. To exclude the possible effects of other drugs, we looked at the 13 cases of pure tricyclic overdose separately. The 6 lethargic patients (grade 1) had a mean total level of 364 ng/ml (range=187–555 ng/ml), and the remaining 7 (grade 2 or 3) had a mean total level of 809 ng/ml (range=189–1732 ng/ml). Because of the overlap in plasma concentrations, patients in coma (grade 2 or 3) showed only a trend toward having higher plasma concentrations than those patients not in coma ($t=1.96$, $p<.10$). However, 5 of the 6 cases in the study with plasma levels greater than 900 ng/ml were in grade 2 coma or worse regardless of whether the ingestions were pure or mixed.

Of the 21 patients who had ECGs on admission, 19 demonstrated prolonged QT interval, 7 had a widened QRS complex, and 7 manifested abnormal ST segments and flat T waves. Of these patients, 14 had at least one subsequent ECG. For 6 patients (including 5 with QRS widening) the ECGs reverted to normal, and the remaining 8 patients still demonstrated a prolonged QT interval at the time of their last ECG (i.e., 24–48 hours after admission). Prolonged PR intervals and right bundle-branch block were each seen in only 4 patients. Arrhythmias were not observed; however, our patients did not always have continuous monitoring of their ECG.

When the mean total tricyclic level for patients with a widened QRS complex (821±180 ng/ml) was compared with that for patients without a widened QRS complex (396±67 ng/ml), the difference was significant ($t=2.71$, $p<.02$). The same statistical comparison performed for the other ECG parameters showed the difference in means not to be significant. Furthermore,

[1]All samples had already been submitted to our own clinical laboratory for routine clinical chemical and/or toxicological analyses required for patient care, and no samples were drawn solely for analysis of plasma tricyclics. The plasma remaining after such routine analyses was frozen (−15°C) until the time of analysis for tricyclics. This protocol was approved by the Yale Human Investigations Committee and the National Institute on Drug Abuse.

[2]A table of data is available from Dr. Bailey on request.

[3]Grade 1=lethargic but arousable with nonpainful stimulation; grade 2=responsive to painful stimulation only; grade 3=nonresponsive to painful stimulation.

when the total tricyclic levels were compared with the magnitude of each ECG parameter using the Pearson product-moment correlation method, no significant correlation was noted.

All patients in this series recovered completely, including 3 who suffered cardiac arrests. Treatment consisted of supportive care alone. One patient also received parenteral physostigmine.

COMMENT

Previous studies of tricyclic overdose have predominantly been single-case reports. Recently, Spiker and associates (6, 14) reported two series of tricyclic overdose in which plasma levels were compared with physical findings and ECG changes. In the first series only the duration of the QRS complex was strongly correlated with total tricyclic levels; more specifically, levels greater than or equal to 1000 ng/ml were associated with a QRS interval greater than or equal to 0.1 second. Plasma levels correlated weakly with maximum pupil size but did not correlate with maximum heart rate, lowest blood pressure, degree of unconsciousness, or changes in the PR interval or ST-T wave of the ECG. In the second series, Spiker and associates noted that mean tricyclic plasma levels were significantly higher in patients who died, had a cardiac arrest, required respiratory support, were unconscious, had a grand mal seizure, had a ventricular rate greater than or equal to 120/minute, had cardiac arrhythmias, had a QRS interval greater than or equal to 0.1 second, or had bundle-branch block.

Our study is subject to several limitations. The patient population consisted only of those who were considered to have taken an overdose serious enough to warrant hospitalization on a medical ward. We do not have information on the less seriously ill patients who were not hospitalized, nor do we have preoverdose baseline data (e.g., ECG pattern) to compare with the data following overdose. It is possible that tricyclic plasma levels correlate best with the difference between baseline parameters and those monitored after overdose. For instance, after therapeutic doses of nortriptyline, Ziegler and associates (17) demonstrated a significant relationship between plasma levels and the increase in heart rate above predrug baseline values. Our patients also varied in the elapsed time between ingestion of the overdose and arrival at the hospital where plasma samples were obtained, and some had taken small amounts of other drugs as well. Nevertheless, these are exactly the conditions that the clinician faces when having to make judgments about the care of such patients in the emergency room. Patients arrive in the emergency room at varying times after the overdose. The history is often vague as to the precise amount of tricyclic ingested or the types and amounts of other drugs taken, and rarely are there baseline data to compare with the patient's ECG and physical findings after the overdose.

A review of the literature clearly indic[illegible] dividual variations in plasma concentrat[illegible] therapeutic doses. In healthy individual[illegible] tion is largely under genetic control (18, [illegible] plasma tricyclic concentrations are not u[illegible] to adjust dosage, and it is not uncommo[illegible] receiving chronic therapeutic doses to [illegible] total plasma tricyclic concentrations in [illegible] as observed after overdose. Half of ou[illegible] total tricyclic levels that approached thos[illegible] ter therapeutic doses (11, 12, 20, 21), and [illegible] had higher levels. Therefore, using [illegible] plasma levels alone to distinguish a pa[illegible] acutely ingested an overdose from one [illegible] therapeutic dose is difficult because of [illegible] overlap in plasma concentrations in thes[illegible] tions.

As a means of differentiating these c[illegible] noted that 21 of our 30 patients had P M[illegible] than or equal to 2.0 (mean± SE=4.6 ±0[illegible] contrast to a P/M ratio less than 2.0 o[illegible] tients stabilized on therapeutic doses (1[illegible] In a report by Gram and associates (2[illegible] P/M ratio was 0.82 (range=0.09 to 2.5) [illegible] maintained on therapeutic doses of imi[illegible] larly, a study of Braithwaite and asso[illegible] vealed an average P/M ratio of 1.17 (ran[illegible] in 15 patients treated for 6 weeks with [illegible] amitriptyline. Although they did not co[illegible] our calculation of this ratio from the dat[illegible] associates (6) demonstrated a P/M rat[illegible] equal to 2.0 in 11 of 12 patients with pu[illegible] or imipramine overdose (range=0.41 t[illegible] much higher ratios following overdose p[illegible] insufficient time for mono-*N*-demethylat[illegible] ent drug.

A parent drug-to-metabolite ratio gr[illegible] equal to 2.0 is more meaningful than the [illegible] cyclic level for the diagnosis of an acute [illegible] presence may be of particular value in [illegible] overdose when the tricyclic level is in t[illegible] served after therapeutic doses and the[illegible] or physical findings characteristic of to[illegible] trast, a P/M ratio less than 2.0 is more c[illegible] high steady-state plasma levels follow[illegible] dosages in spite of ECG or other clinic[illegible] toxicity. Being able to distinguish these t[illegible] is important for the acute management [illegible] well as having implications for their lo[illegible] ment. Patients who have acutely overd[illegible] quire either medical or psychiatric hospi[illegible] in the future they may need particularly c[illegible] tion in times of stress. On the other hand[illegible] levels or toxicity following a therapeut[illegible] require the patient's hospitalization on a [illegible] and a reduction in dosage, but psychi[illegible] ization is probably not a consideration [illegible] P/M ratio greater than or equal to 2.0 stro[illegible] a tricyclic overdose, its absence does n[illegible] exclude it.

The limited relationship between total plasma levels and either physical findings or most ECG changes was disappointing. This was consistent with the earlier report by Spiker and associates (6) but in contrast to their later report (14). When we analyzed the 13 cases of pure overdose, the patients in coma did not have a significantly higher plasma level. Nevertheless, 5 of 6 patients with plasma levels greater than 900 ng/ml were in coma. One possible explanation for this limited relationship is that an acute overdose of drug does not represent a steady-state condition. Tissue tricyclic levels may be transiently higher than plasma levels (22).

The single most common finding in our series was a prolonged QT interval; however, it did not correlate with plasma concentrations of tricyclic, nor did it always return to normal within 24 to 48 hours following admission. Widening of the QRS complex occurred in 7 patients and was associated with significantly elevated total plasma concentrations. This is consistent with the observations of Spiker and associates (6) but, unlike these authors, we found that 6 of our 7 patients with QRS widening had levels less than 1000 ng/ml. Of clinical importance, the QRS interval had returned to normal within 24 to 48 hours in all 5 patients for whom we had follow-up ECGs. Bigger and associates (23) have proposed tricyclics as possible antiarrhythmic agents because of their "quinidine-like effect" in widening the QT interval and thereby increasing the refractory period of the ventricle. In therapeutic doses quinidine prolongs the QT interval; in toxic doses it increases the duration of the QRS complex (24). We feel that, following a tricyclic overdose, widening of the QRS complex (i.e., QRS greater than 0.1 second) may be viewed as an index of serious cardiotoxicity that resolves with falling plasma levels, whereas a prolonged QT interval represents a more sensitive indicator of tricyclic effect that takes longer to return to normal limits.

Unlike many other drug poisonings (e.g., barbiturate, ethanol, and salicylate), where drug levels represent a cornerstone of clinical management, tricyclic overdoses cannot be judged as to their seriousness simply by evaluating the plasma levels. We found that a parent drug-to-metabolite ratio greater than or equal to 2.0 is associated with an acute overdose and may be useful in differentiating an overdose from a therapeutic dose with toxicity and a high steady-state plasma level. Monitoring the ECG appears to be a more cost-effective method and possibly more relevant parameter for gauging the seriousness of the overdose. Prolonged QRS complex, in addition to arrhythmias, is associated with significantly increased tricyclic plasma levels and represents serious cardiotoxicity.

Paradoxical Reaction to L-Dopa in Schizophrenic Patients

BY MURRAY ALPERT, PH.D., ARNOLD J. FRIEDHOFF, M.D., LUIS R. MARCOS, M.D., AND FLORENCE DIAMOND

The authors administered 6 g of L-dopa to 8 schizophrenic patients and 750 mg of chlorpromazine to 7 schizophrenic patients. Chlorpromazine showed only a modest advantage over L-dopa and only on some Brief Psychiatric Rating Scale factor scores, and at maximum dosage the thought disturbance factor score in the L-dopa-treated group was not worse than at baseline. The results suggest that L-dopa is associated more with toxic than with schizophreniform symptoms and that there is adaptation to its effects. The authors discuss implications of these findings for the dopamine hypothesis of schizophrenia.

ALTHOUGH DIRECT SUPPORT for the dopamine hypothesis of schizophrenia has remained elusive (1, 2), there is a substantial body of evidence consistent with the major indirect prediction of the hypothesis: Agents that reduce central dopamine action tend to be therapeutic.

The converse prediction, the expectation that schizophrenics will be differentially sensitive to agents that increase central dopamine, also has considerable support. However, there have been a number of studies in which L-dopa has been administered to schizophrenic patients with results that have not been entirely consistent with the dopamine hypothesis. Unfortunately, these reports are difficult to interpret because of methodological differences among the studies.

LITERATURE REVIEW

For example, in an early study, Yaryura-Tobias and associates (3) reported on 4 schizophrenic patients who showed extrapyramidal side effects while on neuroleptic medication despite the use of anticholinergics. Their interest was in evaluating the efficacy of L-dopa on the extrapyramidal side effects, and, continuing the neuroleptic treatment, they discontinued anticholinergic medication [illegible] L-dopa treatment. They reported mark[illegible] tion of mental status with no improve[illegible] worsening of extrapyramidal side effects

Two characteristics of this study sho[illegible] mind while one is considering these [illegible] tient population was selected for the pre[illegible] pyramidal symptoms and treatment [illegible] cholinergics had been stopped just before [illegible] regard to the first issue, Crowley and ass[illegible] ported that patients who developed e[illegible] side effects while taking neuroleptics [illegible] amounts of free dopamine in their urine [illegible] tiation of the antischizophrenic medic[illegible] tients who did not develop extrapyramid[illegible] and Chase and coworkers (5) found that [illegible] nal fluid concentrations of homovanillic [illegible] droxy-indolacetic acid were not as eleva[illegible] thiazines in a group of schizophrenics w[illegible] drug-induced extrapyramidal side effects [illegible] tion of a group of schizophrenics with e[illegible] symptoms not responsive to anticholin[illegible] have produced a biologically unique study [illegible]

In regard to the second issue men[illegible] abrupt termination of anticholinergics j[illegible] study also may have influenced the e[illegible] noted that abrupt termination of anticho[illegible] have negative effects on the clinical pic[illegible] Fleming and associates (7) reported di[illegible] the relationship between the abrupt te[illegible] anticholinergics and L-dopa. They studi[illegible] receiving fluphenazine decanoate plus [illegible] hydrochloride. Maintaining this schedul[illegible] 3–5 g/day of L-dopa, they found no imp[illegible] extrapyramidal side effects but, rather, s[illegible] of improved mental state. However, whe[illegible] idrine was replaced by a placebo, the[illegible] oration in both mental state and ex[illegible] symptoms. Thus, the effects Yaryura[illegible] associates (3) attributed to L-dopa may [illegible] more complex mechanisms.

There have been a number of recent re[illegible] tive therapeutic effects of L-dopa on sch[illegible] tients. These reports have been based on [illegible] (8–11) and controlled (7, 12, 13) studies, [illegible] 316 chronically hospitalized schizoph[illegible] and have found positive therapeutic effec[illegible] in the areas of communication and rapp[illegible] dopa was added to the treatment regime[illegible] it appears that L-dopa—as little as 600 mg [illegible]

up to 5 g/day (7) and in study periods as brief as 2 weeks (9) or as long as 18 months (11)—may actually be therapeutic, at least in relation to deficit schizophrenic symptoms. There is also a report (14) suggesting that schizophrenic children with autistic features may be helped by L-dopa.

Angrist and associates (15) studied the behavioral effects of L-dopa on 10 relatively acute schizophrenic volunteers with mixed diagnoses who were taking only chloral hydrate or sodium amytal. They interpreted their results as being consistent with the prediction, based on the hyperdopamine hypothesis of schizophrenia, that L-dopa should cause behavioral worsening. However, despite their use of higher doses (up to 6 g/day), they felt the intensity of the effects noted was somewhat less than that reported by Yaryura-Tobias and associates (3), who used doses of up to 2.6 g/day. Their report contained a brief description of the course of the response to L-dopa for each of the subjects, and it is interesting to note that worsening of symptoms was not always monotonic. For patient 3, depression and suicidal ideation cleared at 1,500 mg/day, whereas patient 4 showed disappearance of auditory hallucinations at 5000 mg/day.

Our interest in the action of L-dopa in schizophrenia grew out of our exploration of a novel treatment approach in tardive dyskinesia (16–18), a condition thought to result from supersensitivity of dopamine receptors consequent to prolonged neuroleptic blockade. Assuming that supersensitivity is a biphasic process, we attempted to reduce the sensitivity of dopamine receptors by increasing the amount of available transmitter. To achieve this, we treated our volunteers with L-dopa. Early in the treatment we noted some worsening of both mental condition and dyskinetic symptoms, which had been expected. After some weeks, in a number of cases maintained on a fixed dose of L-dopa we observed a salutary habituation and reduction in dyskinetic symptoms, with the maximum response occurring after the L-dopa was discontinued. In several patients the chronic schizophrenic process appeared to follow the same course as the dyskinesia.

Prior reports on the use of L-dopa have not been designed to reveal whether adaptation to the behavioral effects occurred as the L-dopa was continued over a period of time, nor have comparison groups been treated with neuroleptics in parallel and evaluated off drug at termination. Finally, when behavioral worsening with L-dopa has been reported, it has been difficult to determine whether the schizophrenic process has become more florid or whether a toxic process has been superimposed. To further evaluate these questions, we initiated the following pilot study.

METHOD

Subjects

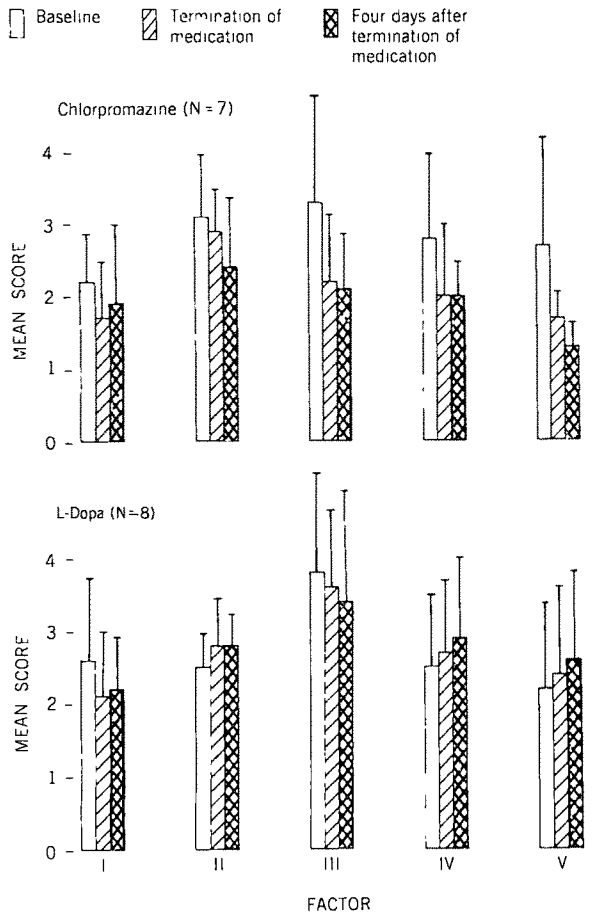
Newly admitted schizophrenic volunteers below the age of 55 were drawn from the adult inpatient services of Bellevue Psychiatric Hospital. Diagnoses were made independently by ward clinicians and by a clinician with the research group and were based on DSM-II definitions (19). All of the patients had at least one prior admission for the same condition. Patients with complicating medical or drug- or alcohol-abuse histories were excluded. All patients signed consent forms after being informed of the study's research nature and treatment risks.

Eighteen patients were randomly assigned to either the chlorpromazine or L-dopa group. One patient in the L-dopa group was lost from study because of persisting nausea, and 2 patients were lost from the chlorpromazine group, one because an acute exacerbation of psychotic symptoms in the first week of study made it necessary to depart from the medication protocol and the second for administrative reasons unrelated to the study.

The average age of the chlorpromazine group was 34.0 years, with a range of 21–48 years. It included 4 men and 3 women. Five of the schizophrenic patients were diagnosed as chronic undifferentiated type, one as paranoid schizophrenic, and one as having an acute schizophrenic reaction. The average age of the L-dopa group was 33.9 years, with a range of 26–50 years. It included 4 men and 4 women. Five patients were diagnosed as chronic undifferentiated type and three as paranoid schizophrenics.

Additional information about the subjects is contained in figure 1, which shows that at baseline both groups obtained their highest Brief Psychiatric Rating Scale (BPRS) (20) factor scores in the area of "thought disturbance." However, as is typical with our recently re-exacerbated patients, a broad range of pathology is represented, and all the factors are elevated.

Dose Schedule



Medication was managed by a nonblind psychiatrist and administered in divided doses three times a day. The initial L-dopa dosage was 0.5 g and was increased 0.5 g every other day until day 11 (3 g); at this point it was increased 0.5 g each day until day 17 (6 g). This dose was maintained through day 24, when it was discontinued. Chlorpromazine was started at 300 mg, increased to 450 mg at day 4, to 600 mg at day 6, and to 750 mg at day 8. At day 11 the dose was adjusted at "doctor's choice." Chloral hydrate was permitted throughout. No other medication was permitted for the 5 days before baseline or for the 4 days after the last day of medication.

The Brief Psychiatric Rating Scale was completed by two independent raters at baseline, on the last day of medication (day 24), and after 4 days without study medication (day 28).

RESULTS

Figure 1 presents the average BPRS factor scores for each measurement period and the standard devia-

FIGURE 1
Brief Psychiatric Rating Scale Factor Scores of Schizophrenic Patients Treated with Chlorpromazine and L-Dopa

tions. Two-way analyses of variance were done for each factor; the differences for factor 1 (anxiety-depression) were not reliable for either drug group or treatment period.

For factor 2 (anergia), the main effects were not reliable, but the interaction was ($F(2, 26)=3.58$, $p<.05$). This interaction may be due in part to the chlorpromazine group's score being somewhat higher initially, but it also was influenced by the tendency of this group to continue to improve after medication was cut.

For factor 3 (thought disturbance), there was a reliable group effect ($F(1, 13)=4.24$, $p<.05$) and period effect ($F(2,26)=3.59$, $p<.05$). The chlorpromazine group appeared to progress more quickly, but the L-dopa group also showed monotonic improvement.

None of the differences observed on factor 4 (activation) achieved statistical reliability, perhaps because of some tendency toward increased variance on these scales.

For factor 5 (hostile-suspicious), the main effects were not reliable, but the interaction was ($F(2, 26)=3.48$, $p<.05$). This finding was consistent with the clinical observation of increased anger in [illegible] L-dopa. However, our measurement [illegible] been past the peak of this effect, which [illegible] the failure to find a main effect for this [illegible]

DISCUSSION

The Brief Psychiatric Rating Scale [illegible] dopa-treated patients were only mode[illegible] worse than those of a comparison grou[illegible] treated with effective doses of chlorpr[illegible] there is little in the results to suggest that [illegible] treated group fared less well than a pla[illegible] group would have. On the other hand, [illegible] infrequency of statistically reliable group [illegible] it should be recalled that the groups we[illegible] that a lack of difference cannot be consid[illegible] similarity. (Because the use of L-dopa for [illegible] ic patients is controversial we felt that [illegible] with a small number of patients was neces[illegible] currently conducting a larger study.)

Another possible contributor to the pa[illegible] ferences between the groups on the [illegible] scores may relate to the point at which m[illegible] taken. Earlier in the course of treatment it [illegible] ier to identify the activated, labile, soci[illegible] patient as being on L-dopa. However, [illegible] nation of medication and 4 days afterwa[illegible] ferences were not discriminable and may [illegible] adaptation to the treatment.

It would appear that L-dopa does not [illegible] acerbate schizophrenic symptoms, since [illegible] schizophrenic BPRS factor, which incl[illegible] disorder and hallucinations, actually s[illegible] lowering in the scores of the patients who [illegible] 6 g of L-dopa from their baseline rat[illegible] schizophrenics may be vulnerable to the [illegible] dopa, these effects appear to manifest the[illegible] more diffuse toxic psychosis that is supe[illegible] the schizophrenic illness. We plan additio[illegible] study this issue.

It is not simple to place these findings in [illegible] of the dopamine hypothesis. Following [illegible] sults in a number of attempts to demonstr[illegible] turnover of central dopamine in schizoph[illegible] attention has shifted from presynaptic re[illegible] synaptic mechanisms, possibly including [illegible] in receptor sensitivity (21). An exacerbat[illegible] toms with L-dopa, followed by adaptatio[illegible] observed, is not inconsistent with such [illegible] are planning a study that will include a [illegible] ment period and a data-analytic design, wh[illegible] mit within-patient comparisons of the clin[illegible] with tremographic measures.

The worsening in the clinical condition [illegible] schizophrenic patients after several wee[illegible] doses of L-dopa was less than might be pred[illegible] the dopamine hypothesis. In addition, the [illegible] areas in which worsening occurred are diffi[illegible]

clearly confined to schizophrenic symptoms. Also, we noted some indications of adaptation to the effects of L-dopa; adaptation is not thought to be characteristic of the pathogenic process underlying schizophrenia. In fact, adaptation to L-dopa might have treatment potential considering the positive reports from a number of studies (7–14) in which L-dopa was given in conjunction with neuroleptics. Further study is indicated.

The Social Context of Schizophrenia

BY J.K. WING, M.D., PH.D.

During the past 25 years psychiatry has increased its understanding of the social context of schizophrenia in four major areas. Reasonable reliability can now be achieved in describing and recognizing many of the acute and chronic syndromes, so that comparability can be achieved between different research teams. Much is now known about the proximate social causes of symptoms and disabilities. The relationship between social and pharmacological treatments is now better understood. A more rational approach to the planning and prescription of services and to the counseling of patients and relatives can be made. Each of these lines of advance promises to lead to further progress in the future.

THE PUBLICATION, 25 years ago, of the discovery of a really effective pharmacological method of suppressing the major symptoms of schizophrenia must rank among the great medical advances of this century. Not only did it prove of immense value in reducing the distress and disability suffered by patients but it led to biochemical studies that have already proved fruitful and promise, eventually, to deepen and broaden our understanding of the nature of the condition. No discussion of recent advances in our knowledge of the social causes of schizophrenia or of the social aspects of treatment is complete unless it gives due acknowledgment to the fact that the course and outcome of the disease are markedly altered by drug treatment.

Of course, it should be recalled that the prognosis for schizophrenia was not totally bleak in earlier times. Mayer-Gross (1) described a 16-year follow-up study of patients with schizophrenia admitted to the Heidelberg Clinic in 1912 and 1913. Just over one-third of these patients had made what Mayer-Gross called social recoveries. For 5 years Harris and his colleagues (2) followed patients admitted to the Maudsley Hospital in London for insulin coma treatment between 1945 and 1948. They found that 45% of these patients were socially independent and had few or no symptoms of schizophrenia at 5-year follow-up. In 1961 Brown and his colleagues (3) examined a group of patients first admitted for schizophrenia to 3 English [illegible] tals 5 years earlier, in 1956. The proport[illegible] dependent lives without marked sympto[illegible] phrenia was 56%. The figures cited from [illegible] are not strictly comparable because of [illegible] mortality and the numbers of patients lo[illegible] cause standard methods of defining and [illegible] groups of patients were not used. How[illegible] suggest a considerable improvement in c[illegible] of which seems to have taken place bef[illegible] pharmacological treatment and part sinc[illegible] possible that a further improvement [illegible] since 1961.

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Wing is Professor of Social Psychiatry and Director, MRC Social Psychiatry Unit, Institute of Psychiatry, London, SE5 8AF, England.

THE IMPORTANCE OF DIAGNOSIS

Any historical perspective raises the p[illegible] comparability of clinical diagnosis. Thi[illegible] area in which we can claim considera[illegible] progress. Advances have been made in ac[illegible] munication between psychiatrists worki[illegible] times and in different parts of the worl[illegible] United States-United Kingdom Diagnos[illegible] and the World Health Organization Inte[illegible] Study of Schizophrenia (7) have demons[illegible] most characteristic central syndromes of [illegible] phrenia are universally recognized by ps[illegible] though there is less clinical agreemen[illegible] much more should be included under the [illegible] label. The adoption of standard techni[illegible] search purposes does not, of course, elim[illegible] tual differences, but it makes them muc[illegible] vestigate and provides a way of achievin[illegible] stricted comparability. In particular, [illegible] recognize syndromes reliably allows the [illegible] a wide range of biochemical, genetic, p[illegible] cal, and epidemiological work, and this [illegible] most promising ways to expand future [illegible]

Already, of course, we can be sure tha[illegible] of schizophrenia is not homogeneous. I[illegible] rank symptoms described by Schneider [illegible] temporal lobe epilepsy, amphetamine ps[illegible] coholic hallucinosis. Paranoid syndro[illegible] first-rank symptoms are very diverse, r[illegible] subcultural state characterized by exciter[illegible] secutory delusions colored by local be[illegible] tions such as morbid jealousy or "pari[illegible] lans." A wide variety of somatic and [illegible] factors may be involved. Conditions that [illegible] terized by catatonic symptoms but not by [illegible]

0002-953X/78/0011-1333$0.60 © 1978 American Psychiatric Association

hallucinations (rather rare in the acute form nowadays) may be due to encephalitis or other brain disease as well as to schizophrenia. Accurate description of the acute symptoms and signs is still extremely important and will pay dividends for the future.

Progress has also been made in defining and reliably measuring some of the more chronic symptoms that occur in schizophrenia. One set of such symptoms—the "chronic poverty syndrome"—comprises flatness of affect, poverty of speech, slowness, underactivity, social withdrawal, lack of motivation, and impaired ability to communicate using nonverbal language. These symptoms have a great effect on work output at simple industrial tasks and on social performance more generally (8). Another chronic syndrome includes incoherence of speech and unpredictability of associations; the individual does not seem to be able to think to a purpose but goes off on sidetracks, giving the impression of confusion and incompetence.

The relationship between the acute and the chronic syndromes has long been a matter of controversy. Some theorists have thought that specific kinds of delusional experience were primary, but others, like Eugen Bleuler, regarded flatness of affect and loosening of associations as "fundamental." A multigene theory, together with one taking into account the action of a variety of environmental precipitants (somatic, psychological, and social) could comprehend both points of view and link the dimensional with the categorical approach as well. The traits underlying both acute and chronic syndromes may be widely distributed. The main point about a diagnosis, however, is to suggest to the clinician theories that might be helpful when applied in practice, i.e., theories that will predict a useful form of treatment, prevention, or management or, at the very least, suggest a prognosis. None of the concepts of schizophrenia in vogue at present is firmly grounded in a set of linked and tested theories in the same way as diabetes mellitus, for example, although there are many analogies between the two concepts and we may hope that one day our knowledge of schizophrenia will equal our knowledge of diabetes. It is therefore necessary to proceed to some extent empirically.

We know that the acute syndromes usually respond to phenothiazine treatment, whereas the chronic syndromes respond less well. We know that the acute syndromes, particularly when precipitated by organic factors such as amphetamine or alcohol, are less likely to be preceded or followed by the chronic syndromes. We know that social withdrawal often accompanies chronic depression, mental retardation, chronic physical disability, Asperger's syndrome, and severe social deprivation. Moreover, mild degrees of affective blunting or of "thought disorder" cannot be recognized reliably. These are good empirical reasons why any theory linking acute and chronic schizophrenic syndromes should not be applied in practice, except with great circumspection. In particular, the supposed presence of chronic syndromes should not lead to a regime of treatment suitable only for the acute syndromes if the latter are absent, and especially if they have never been present. Terms such as "simple," "pseudoneurotic," "pseudopsychopathic," "latent," or "sluggish" schizophrenia should not be made to carry too much therapeutic meaning. Still less should the spectrum concept be used clinically. In my view, failure to understand this basic distinction has contributed to practices that can indeed be criticized (9).

SOCIAL CAUSES OF SCHIZOPHRENIA

The second area in which considerable progress has been made is that of the social causes of the characteristic acute and chronic syndromes. The simplest way to study these is to look for immediate effects of varying social conditions. It has been well documented, for example, that some patients living in a sheltered environment relapse very quickly when they are exposed to a program of rehabilitation that asks too much of them (10–13). In other words, social pressure, even when well intentioned, can be harmful. Brown and Birley (14) demonstrated an increase in the frequency of certain life events for schizophrenic patients compared with control groups during the few weeks immediately before the first onset or an acute relapse. Other studies (15, 16) have shown that patients who return home after discharge from the hospital to live with a relative who is hostile, critical, or emotionally overinvolved tend to have a very high relapse rate compared with those whose relatives are more accepting and emotionally neutral.

These three very different types of social precipitant have in common the fact that they occur in close contiguity to the onset or acute relapse of schizophrenia. There has long been a theory that the relatives of people with schizophrenia are in some way implicated in the original causation of the disease (17). Very few empirical studies have been carried out to test this hypothesis, and, in any case, the methodological problems are immense. Studies of identical twins brought up together or apart provide little convincing evidence (18). The best work methodologically is that by Wynne and his colleagues (19, 20) suggesting that communication deviances are common in the parents of patients with schizophrenia, although this has no necessary bearing on origins in childhood. However, this clear-cut result has not been replicated in a recent very careful study in England (21), and it may be that the reason, at least in part, is that the criteria for diagnosis in the two series were quite different. As for the really passionate advocates of various forms of the early environment model of causation, it is difficult to understand where the strong motivation to believe such theories springs from in the absence of any substantial supporting body of evidence.

Reverting to the three very different types of factors that seem to be clearly and immediately related to relapse or first onset, what they appear to have in com-

mon is a degree of social overstimulation. Other social causes of schizophrenic symptoms seem to work in a very different way. The clinical poverty syndrome, for example, tends to become much more pronounced under conditions of social understimulation. The classical example is the back ward of the old-fashioned mental hospital, where severely disabled schizophrenic patients with little capacity for spontaneous communication were left to their own devices and spent a very large proportion of their waking day doing absolutely nothing. They became very much more withdrawn and underactive and apathetic. Within limits, this effect can be reversed. An increase in the richness of the social environment leads to a decrease in the poverty syndrome (8, 13, 22). This result is not true only of the situation in the back wards. It has been found that schizophrenic patients are vulnerable to such effects wherever they are found—in hostels, hotels, group homes, day centers, sheltered communities, centers for the destitute, in lodgings, or in a patient's own home. In one 5-year follow-up study (3) it was found that, among patients who were unemployed and living at home, the length of time spent doing absolutely nothing was of much the same order as among long-stay patients in a hospital with a poor social environment.

If these studies are accepted as providing a basis for rational social treatment, there are two major problems: 1) the reduction of an excessive level of social withdrawal and other associated behaviors by enriching the social environment without provoking an acute relapse, and 2) the reduction of an excessive level of social stimulation without encouraging undue dependence.

To summarize the processes involved: many patients who experience an attack of acute schizophrenia remain vulnerable to social stresses of two rather different kinds. On the one hand, too much social stimulation, experienced by the patient as social intrusiveness, may lead to an acute relapse. On the other hand, too little stimulation will exacerbate any tendency already present toward social withdrawal, slowness, underactivity, and an apparent lack of motivation. Thus the patient has to walk a tightrope between two different types of danger, and it is easy to become decompensated either way. The difficulty in thinking and the inability to communicate verbally and nonverbally will be most evident in interactions with close kin, for example, and will be exacerbated in conditions of anxiety and high arousal.

Families might provide protective or provocative settings; there is no general rule. The same is true of nonfamily environments. However, the first onset usually occurs within a family setting, and there is a natural tendency on the part of relatives toward normalization, which can lead to further intrusion, particularly if the patient withdraws in natural reaction. The patient may try to explain the abnormal experiences in terms of hypnotism, thought transfer, witchcraft, or other subculturally acceptable ideas. The more intrusive the environment, the less the pati[illegible] withdraw and the more the symptoms ar[illegible] and provoked. Being admitted to a hospi[illegible] ing off alone may provide relief simply by [illegible] degree of social stimulation.

After several attacks, the patient may [illegible] with his or her experiences and find (whe[illegible] consciously formulates this or not) th[illegible] withdrawal is protective. Relatives, too, [illegible] themselves just what degree of stimul[illegible] missible, so that a working solution is a[illegible] tients usually do not wish to be entirely a[illegible] do like to remain in control of the inter[illegible] The role of the relative, however, is a v[illegible] because it is unnatural to acquire the det[illegible] ment and neutrality required; it is much [illegible] fessional people to adopt such a stance [illegible] of handicapped people may easily b[illegible] protective and overinvolved. In the ca[illegible] phrenia, this overinvolvement has spec[illegible] increasing the liability to further break[illegible] this shows itself in such symptoms as w[illegible] iness at night, refusal to eat, or delusion[illegible] relative, a circular effect is set up. The rel[illegible] such reactions on a future occasion.

The alternative temptation for the pat[illegible] draw altogether into contemplation of p[illegible] ences. When a patient is allowed to do so[illegible] stimulating conditions of some large hos[illegible] badly run hostels, in reception centers, [illegible] attic at home, the negative impairments [illegible] and more obvious.

INTERACTION BETWEEN DRUG AND SOCIAL TREATMENTS

Our improved understanding of the in[illegible] tween pharmacological and social treat[illegible] third major area I should like to discuss [illegible] long-stay schizophrenic patients there hav[illegible] indications that drug treatments and soci[illegible] are not alternatives but must be used to[illegible] each other. The better the environmenta[illegible] the less the need for medication; the poor[illegible] milieu, the greater the need (or at leas[illegible] drugs (8, 13, 16, 22). A similar generaliz[illegible] made, although the details are different, [illegible] methods of handling acute breakdown.

If phenothiazine drugs work, at least i[illegible] ducing a high level of physiological a[illegible] they should be most effective in condit[illegible] overstimulation; there is some evidence [illegible] (15, 16). It has been suggested (16, 25) [illegible] who live in "low-emotion" families can [illegible] (except for the operation of accidental si[illegible] without taking preventive medication. L[illegible] colleagues (26), for example, have recent[illegible] schizophrenic patients sitting quietly by t[illegible] their own homes have a high arousal level[illegible]

by skin conductance. If a "high-emotion" relative enters the room there is no change in arousal level. If a "low-emotion" relative enters, the high arousal habituates toward normal. This work needs to be repeated, but, if it holds true, it suggests that some relatives have a calming and supporting effect, similar to the protective effect of a good hospital, hostel, or therapist. On the whole, the need for medication is minimized when the patient is living in optimal social surroundings. The optimal environment is structured, with expectations geared precisely to the level of performance that the patient actually can achieve, or perhaps a little above, but with supervision that is not emotionally involved. Complex decision making is particularly difficult for patients and tends to rouse their anxiety or their withdrawal. Control of the level of social stimulation must be left to some extent in the patient's hands. A relationship of trust and confidence, whether with relatives or with professional staff, is most likely to develop when these conditions are optimal.

This kind of explanation may also be applied to observations to the effect that schizophrenic patients in some developing countries appear to have a better prognosis than elsewhere (27, 28). Factors such as the degree of social overstimulation (and the amount of face-to-face contact between close relatives that fosters such stimulation) may vary considerably in different cultural settings, as may the impact of more accidental social pressures. If so, it can be hypothesized that the lower the sum total of the environmental pressures, the less will be the need for pharmacological forms of treatment.

A great deal remains to be explained about the acute and chronic syndromes. The mechanisms whereby first-rank symptoms, such as thought echo or "thoughts spoken aloud," which are direct descriptions of basic experiences with very little elaboration, can be explained in terms of overarousal, phenothiazine action, or cerebral pathology remain obscure. Recent advances in pharmacology and biochemistry are so promising that it is clear that links will have to be made. Meanwhile, the formulation put forward here has obvious relevance to problems of management.

THE MANAGEMENT OF SCHIZOPHRENIA

The fourth area in which advances have been made and opportunities opened for further progress is that of "management," including the planning and prescription of services. So far, we have considered the reactivity of the acute and chronic syndromes and have not dealt with their effects on the individual's level of social functioning. Two more general factors need to be considered: extrinsic disadvantages and adverse secondary reactions.

Chronic impairments contain a component that is "intrinsic" and a component that is reactive. From a purely practical point of view, an intrinsic impairment is one that will not go away, no matter what biological, psychological, or social factors are brought to bear therapeutically. Of course, we can never be certain, in theory, that we have tested the limits of treatment, and circumstances sometimes change in a way that surprises even the most astute clinician, so that it is never wise to give up hope of improvement. However, to deny that severe and chronic intrinsic impairment can exist must do more harm than good. It is only by recognizing and studying disabilities that it is possible to find ways of compensating for them.

"Extrinsic" factors are those which would have been disadvantageous whether or not the individual had become ill. Someone born in a large family in a poor area with inadequate housing and high unemployment is socially disadvantaged. If this person has few assets in the way of vocational skills, intelligence, social attractiveness, family support, and so on, he or she is not well prepared to cope with chronic illness of any description, let alone schizophrenia. However, the socially disadvantaged are more at risk for developing all sorts of diseases, schizophrenia being one of them. There has been a long discussion of whether socially disadvantageous conditions are likely to cause schizophrenia, or whether the high rates observed under such conditions are due to a preexisting drift. Intrinsic impairments often precede the first acute attack. In such cases the prognosis is less likely to be favorable. The balance of the epidemiological evidence at the moment is in favor of the view that much of the association noted between the onset of acute schizophrenia and factors such as social class, marital status, migration, and social isolation is due to selection rather than to stress (29). On the other hand, it is also clear that a disadvantaged background has an adverse effect on the course of the illness because of the lack of social support. This is why an attempt to increase the number of assets—by providing social skills and vocational training, by creating a graded series of supportive social environments, by counseling in methods of self-help, and so on—is of such importance.

Adverse secondary reactions occur when the handicapped or disadvantaged individual's self-attitudes, confidence, and expectations suffer to an extent that is out of proportion to the cause. Such factors are particularly important in psychiatric disorders, and they depend a great deal on the reactions of important people in the affected person's social environment. Relatives, employers, workmates, friends, and professional people reflect to the patient an indication of personal worth and status. Severely handicapped people have to opt out of certain responsibilities, and others have to take them on. If the others are professionally trained for the job there can develop what Goffman (30) called a staff-client split, each side taking up stereotyped attitudes toward the other. The longer the client experiences dependence, the more he or she may come to prefer it. Staff, in turn, may exaggerate the severity of the intrinsic component in impairment, and thus a vicious circle is set up, with unnecessary

dependence developing as well as that which is unavoidable.

The acceptance by handicapped persons of limitations that are not actually necessary is the essence of secondary reaction. The most obvious example is institutionalism, at the heart of which is a gradually acquired contentment with life in the institution that culminates in the individual's no longer wishing to live anywhere else. Institutionalism is thus caused partly by a reflection back to the handicapped person of his or her own altered status as a human being. He or she is seen as a patient, rather than as an employee, a father, a mother, a customer, or a companion. The patient role is a constricted one, replacing many others that the patient might have been able to undertake. Partly, however, institutionalism results from forces in the patient—his or her own previous experience of illness, self-confidence, potential for developing alternative skills, and determination to achieve independence (8). Now that few people stay in the hospital for more than a few weeks, other types of adverse secondary reaction are more common—for example, attitudes of despair or apathy arising from experience of unemployment, solitary living, social rejection, poverty, and even destitution.

Perhaps the most striking change that has occurred in psychiatric practice during the past 25 years, as a result of the new methods of social and pharmacological treatment, is the decrease in the numbers of patients living in large mental hospitals. When it first became clear that this trend was firmly established, some psychiatrists began to think that most of the symptoms and the disability found in long-stay patients were actually caused by being in the institution. Thus, preventing people from entering the hospital at all would prevent much of this morbidity altogether. At the same time, sociologists were showing that, in some areas of the United States, people were being given a diagnosis of schizophrenia and admitted to a hospital even though their problems appeared to be social rather than medical and the functions of the hospital seemed custodial rather than therapeutic (31). The results were overgeneralized, but there followed a revulsion against the use of institutions.

In some parts of the United States it has become as hard to get into a hospital as, in former days, it had been hard to get out of one. An ideal of "community care" was set up instead, which in its most extreme form excluded the use of hospitals altogether. This period has been followed, in its turn, by a period of reappraisal. It is now clear that some patients continue to be severely disabled and vulnerable to relapse, even though they have spent only a brief time in the hospital or even no time at all. A small but important "new long-stay" group is accumulating (32). It is also clear that nonhospital services can suffer from deficiencies quite as great as those of hospitals (33). A good hospital is better than a poor hostel, nursing home, or hotel and is just as much a part of community care. Even the concept of community itself can be challenged, when the patient has no social roots, is markedly [illegible] and is unable to make spontaneous soc[illegible]

Three principles of service organizat[illegible] been accepted as being basic to a goo[illegible] service: that it should be responsible for [illegible] geographical district, comprehensive [illegible] with a very wide range of needs, and [illegible] tegrated to ensure adequate commun[illegible] agencies and not block or delay a patien[illegible] one part of the service to another. The a[illegible] organized in this way is to prevent, d[illegible] tain disease and disability by providing f[illegible] agnosis, therapy, rehabilitation, and s[illegible] calling the attention of other respons[illegible] effective means of prevention (34).

These considerations are particularly [illegible] schizophrenia. Earlier, I drew the anal[illegible] tes mellitus, and the concept of the "[illegible] a chronic physical disease is very appro[illegible] to be considered from three points of [illegible] patient; that of the patient's relatives an[illegible] immediate social environment on whe[illegible] well-being and livelihood may depend [illegible] professional people, administrators, [illegible] who provide, plan, and control acces[illegible] Each group sees a different set of prob[illegible] fails to appreciate the difficulties face[illegible]

The principles of management in [illegible] based on recently acquired knowledg[illegible] elaborated elsewhere (35). They requ[illegible] tion of skills that some psychiatrists, [illegible] tional therapists, and social workers co[illegible] sess. Above all, they require a willi[illegible] from patients and relatives, who are the [illegible] the essential information on which skil[illegible] must be based. Part of the peculiar diffe[illegible] ing schizophrenia is that it lies somew[illegible] conditions like blindness, which, alth[illegible] handicapping, do not interfere with an i[illegible] pacity to make independent judgments ab[illegible] own future, and conditions like severe m[illegible] tion, in which it is clear that the indiv[illegible] be able to make such independent judgm[illegible] frequently a fluctuating degree of insig[illegible] ty. In some cases the fluctuations appe[illegible] obvious pattern. They are then quite [illegible] and environmental circumstances seem[illegible] fact that the impairments are invisible [illegible] lems even more difficult, since neighb[illegible] and even, unfortunately, some profess[illegible] deny their existence altogether.

Nevertheless, a good deal is now k[illegible] social and pharmacological reactivity of [illegible] chronic syndromes and the way adverse [illegible] actions develop. This means that it is p[illegible] ence the course of schizophrenia for t[illegible] deed, in a great many areas, some par[illegible] already operates effectively to minimize [illegible] maximize assets, or relieve burden. If it [illegible] to put together a service that was effect[illegible]

parts, instead of only in some of them, a great deal of illness, handicap, and suffering would be prevented. Such a service would have to include a range of sheltered day and residential environments. The elements of a responsible, comprehensive, and integrated service are well-known on both sides of the Atlantic (34, 36).

One further point deserves emphasis because it has been insufficiently appreciated hitherto. This is that the relatives of schizophrenic patients are nowadays the real primary care agents. They and the patients deserve better counseling (37). The most important and most difficult requirement, for patient, relative, and therapist alike, is to be realistic. If the therapist expects too much (endeavoring, perhaps, to fit the patient into the straitjacket of some untested theory), he or she can very easily make the patient worse (10–13). It may seem reasonable to submit the patient to an intensive regimen of social skills training, rehabilitation, or social activation on the theory that invisible impairments need not be considered, but, although it will sometimes work, it often will not.

It should always be remembered that there is a suicide rate in schizophrenia. If the patient has severe intrinsic impairments they will usually be obvious, and it may be worthwhile, for example, to accept work in a sheltered setting where only part of the social role need be adopted. A neutral (not overemotional) expectation to perform up to *attainable* standards is the ideal. This rule, if difficult for the specialist to adopt, is a thousand times more difficult for relatives. Nevertheless, we should be humbled to recognize that a large proportion of relatives, by trial and error, do come to adopt it without any help from professionals. The patient will have the greatest chance of acquiring insight if those around him or her are realistic in spite of everything. This is why skilled counseling (which means much more willingness by professionals to learn from relatives and patients) is the essence of good management.

Our attitudes to cancer have changed fundamentally during the past decade. Opinion leaders are willing to say that they have been treated for it and that they can live with it. This is not yet true for schizophrenia. Doctors themselves are still frightened of the word. Because the most effective methods of management and the services to back them up are not yet universally available, known, or applied, it is rare for the condition to be frankly and realistically discussed. Public opinion remains ill-informed and prejudiced. But just as the results of treatment have dramatically improved during the past quarter of a century, so the simple application of our present knowledge could produce a further substantial step forward. We would find that public opinion moved forward with us.

Foundations' Fund Prize for Research in Psychiatry

The American Psychiatric Association is inviting submissions for the second annual Foundations' Fund Prize for Research in Psychiatry.

Candidates for the prize should be citizens of the United States or Canada and should be nominated by a sponsor. Sponsors should be members of the American Psychiatric Association. Members of the prize board are excluded from submitting nominations.

The *sponsor* should submit a supporting letter justifying the nomination in detail and summarizing the nominee's research accomplishments.

The *nominee* should submit the following:

1) An up-to-date curriculum vitae,
2) An up-to-date bibliography,
3) A group of representative and thematically linked papers or books published (or accepted for publication) in English and dated within 10 years of the deadline for submission, and
4) A summary statement written by the nominee that emphasizes the principal theme or themes running through the work and its internal cohesiveness and consistency.

Six copies of each entry should be submitted to Joel J. Elkes, M.D., Chairperson, Foundations' Fund Prize Board for Research in Psychiatry, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Entries will be acknowledged but cannot be returned. The award will be presented at the Convocation of Fellows at the APA annual meeting in May 1979.

The deadline for submission is December 1, 1978. Any entry received after that date will automatically be entered for consideration for the 1980 award unless withdrawn by the nominator or candidate.

Automated Treatment for Flight Phobia: A 3½-Year Follow-up

BY MYRON S. DENHOLTZ, M.D., LAWRENCE A. HALL, PH.D., AND EDWARD MANN, PH.D.

The authors contacted 43 patients who had been given audiovisual treatment for flight phobia 3½–5½ years previously. Of the 26 subjects who had flown successfully by the end of treatment, 23 had maintained their ability to fly at follow-up. Eighteen said their attitude toward flying was more positive since treatment, and 21 rated their comfort level while flying as "much better" or "better"; however, only 3 said they were "cured." Eleven patients said the treatment had helped to alleviate other fears or anxieties.

ALTHOUGH BEHAVIOR THERAPISTS have been exemplary in empirically validating their clinical techniques, the long-term follow-up of behavioral treatment programs applied to clinical populations is basically nonexistent. Notable exceptions include work with speech anxiety (1, 2), stuttering (3), obesity (4, 5), and cigarette smoking (6).

The purpose of this study was to make personal contact with subjects who had been treated for flight phobia 3½–5½ years previously to check the stability of the assumed behavior changes and to look for any significant change in those who had failed to improve. In addition, we tested certain assumptions about posttreatment attitude, MMPI findings, and behavior.

ORIGINAL STUDIES

Using the subjectively reported anxiety responses and pleasure responses of 102 subjects, Denholtz and Mann (7) developed a 16-mm sound film and accompanying instructional tape. All of the subjects were shown 160 20-second scenes edited from TV commercials. Eighty scenes were designed to elicit anxiety in subjects with flight phobia, and 80 scenes were expected to elicit pleasurable responses. The 16,320 differential responses on a scale of 0 to 10 allowed hierarchical arrangement of all scenes by computer. We then arranged 27 paired scenes in a progression from low to high anxiety evocation. The pairs consisted of a 20-second anxiety scene followed immediately by a 20-second pleasurable scene and were separated by an identifying printed scene label.

Denholtz and Mann (8) then used this film as treatment. The "therapists" were housewives and college students who had been taught to use the projector, signal devices, and the tape player, which played the prerecorded instruction tape. The instruction tape first induced relaxation and then instructed subjects to press appropriate buttons, which registered the presence or absence of anxiety after the subjects viewed each scene pair. The tape was also used to induce relaxation between scenes. When a scene pair evoked anxiety, it was repeated until there was no reported anxiety, and then the next pair was shown. This procedure was continued until the film was completed, usually in 2–10 half-hour sessions.

There were 3 control groups. The first group, while relaxed, was shown a placebo film that was not related to flying. The second group, while relaxed, was shown the entire treatment film straight through in 6 separate sessions. The third group received treatment without relaxation. Subjects in the 3 control groups who failed to improve in 6 half-hour sessions were transferred to the treatment group.

The significance of this study was that it combined desensitization, modeling, and positive reinforcement in a totally automated audiovisual program and was administered by nonprofessionals who had no contact with the authors. All subjects were given pre- and posttreatment MMPIs. Any subject in whom psychoticism was suggested on the initial MMPI was eliminated from the study. Of the 51 subjects who previously had refused to fly and completed the program, 40 (78.4%) reported being able to fly after treatment. Significant positive changes were also noted on the Taylor Manifest Anxiety Scale of the MMPI for all subjects who overcame their fear of flying. In addition, the successful subjects demonstrated significant positive shifts on 14 of the 24 MMPI scales, whereas there was only 1 positive scale shift in the unsuccessful group. These results suggest that major personality changes can generalize from successful treatment in limited problem areas.[1] Although there was an overall success rate of 78.4% for the 51 subjects completing the study,

there were 30 dropouts from the control groups. The subjects in the control groups were not offered crossover to treatment until they had completed 6 sessions of control group "treatment." Many subjects who did not feel a reduction in anxiety or felt frustrated while watching placebo films dropped out before they could be transferred to actual treatment.

FOLLOW-UP PROCEDURE

We attempted to reach all of the 51 original participants for a semistructured telephone interview; we contacted 43. We asked them how many flights they had taken since treatment and the purpose and social circumstances of those flights and about their emotional comfort while flying, their use of security items, changes in their attitudes toward flying, other generalization effects, and their own assessments of success or relapse. We also recorded their spontaneous comments. The interviews lasted 5–20 minutes and were conducted by a clinician who had considerable experience with phobic patients and who was not part of the original project. All of the subjects contacted were very cooperative and appeared to respond honestly to the open-ended questions.

For this follow-up study, all of the previously treated subjects who were reported in the original papers were classified as behaviorally successful, i.e., had actually flown soon after the termination of treatment; attitudinally successful, i.e., were enthusiastic and had given every indication that they would fly but for financial reasons had not yet been able to purchase a ticket; and unsuccessful subjects.

RESULTS

Maintenance of improvement was determined by the subjects' responses to the questions "How soon after the fear of flying program did you fly again?", "Have you been unable to take any flights since the end of the treatment?", and follow-up questions about each flight taken since the end of the program. Flights were defined as round-trip flights including stopovers.

Twenty-three[2] of the 26 subjects (88.5%) in the behaviorally successful group were currently able to fly. This group had taken numerous flights (median=5, range=1–80). The 3 subjects from the behaviorally successful group who had stopped flying included 2 women who were in individual psychotherapy before entering the program and at the time of follow-up and a third woman who had taken 6 flights with comfort but stopped flying 2 years later after her husband was involved in an airplane crash.

In striking contrast to the behaviorally successful group, both the attitudinally successful and the unsuccessful groups showed little behavioral ga[illegible] measure of success used was subjects' ab[illegible] round-trip flight and their willingness to f[illegible] that flight. Six of the 7 attitudinally succes[illegible] had not flown, and 8 of the 10 unsucces[illegible] contacted had not flown. One of the 2 [illegible] group who were able to fly had subse[illegible] treated individually by a skilled behavio[illegible] ter his failure in the experimental progra[illegible] man's sister died suddenly, which necess[illegible] to a distant state. He described the fligh[illegible] despite preflight tranquilizers and much [illegible] lowing that flight, he would not retur[illegible] stated that he could not fly again. The d[illegible] havior outcomes of the behaviorally suc[illegible] compared to the attitudinally successful [illegible] cessful groups combined was statistical[illegible] (χ^2=21.79, p<.001).

Attitudinal data were elicited by the que[illegible] there been any changes in your attitude [illegible] since your participation in the fear of fly in[illegible] Of the behaviorally successful participa[illegible] tacted who were still flying, 81.8% (18 of 2[illegible] positive change in their attitude. As n[illegible] pected, the 3 relapses in the behaviora[illegible] group reported no change. Four of the [illegible] successful subjects, including the one w[illegible] indicated a positive change in their attitude[illegible] ing. Eight of the 10 unsuccessful subjects [illegible] change in attitude, 1 reported less fear, a[illegible] a more fearful attitude toward flying. Th[illegible] attitudinal changes for the behaviorally su[illegible] jects and the attitudinally successful and [illegible] subjects combined proved to be significa[illegible] p<.01).

Of the 22 behaviorally successful subje[illegible] flying, 15 rated their comfort level wh[illegible] "much better"; 6 as "better"; and 1 [illegible] "worse" although he continued to fly. [illegible] questioning, 3 of the behaviorally succes[illegible] reported themselves as "cured," i.e., they [illegible] of it anymore. The single attitudinally su[illegible] unsuccessful subjects currently flying [illegible] selves as "much better" and "cured," re[illegible]

For data relating to the generalizatio[illegible] treatment, all of the successful subjects [illegible] "Do you attribute any other changes in y[illegible] and behaviors to the fear of flying treatme[illegible] tion, subjects volunteered information th[illegible] terpreted as generalization. Many subje[illegible] regular use of antitension strategies, such [illegible] laxation techniques learned during treatm[illegible] viate other fears or anxieties during the d[illegible] ported a generally more relaxed feeling. [illegible] haviorally successful subjects currently al[illegible] described improvement in other areas, e[illegible] ing of claustrophobic feelings and improve[illegible] cross bridges. The 3 behaviorally succes[illegible] who had relapsed evidenced no generaliz[illegible] 7 attitudinally successful subjects, the o[illegible]

[2]One subject who was away on a flying trip was not contacted personally. Her neighbor reported that she regularly flies without fear.

flying and 2 of the nonflyers showed evidence of generalization. In the unsuccessful group, the currently flying subject who was treated subsequently and 2 of the failures had had some generalization.

To assess the use of security items, an indirect measure of relative insecurity and doubt about the permanence of the improvement, currently flying subjects were asked, "Do you use any security items such as tranquilizers or alcohol before flying?" Further queries determined if they purposefully carried items such as chewing gum, cough drops, mints, a small can of apple juice, etc. Of the 22 behaviorally successful participants who were flying, 10 (45.5%) continued to use security items. The attitudinally successful subjects currently flying relied on security items. The unsuccessful subject who had subsequent treatment and who now flies uses none.

SUBSEQUENT MODIFIED TREATMENT

There appeared to be a more rapid response to treatment and a greater success rate among subjects who had previously viewed the treatment film in its entirety a number of times, i.e., controls who crossed over for treatment after viewing the treatment film under other than optimum treatment conditions (8), and participants in the original evaluation of scenes in 1973 (7) who had returned for treatment. A modified treatment using the film hierarchy and treatment tape was developed and administered by one of us (M.S.D.) in a clinical setting to unselected patients who requested treatment of flight phobia. The criteria for inclusion in this group were the absence of elevated profiles on the psychotic tetrad scales of the MMPI and an unwillingness to fly even if accompanied by a family member. Each patient was taught relaxation by tape-recorded instructions that he or she used at home for a minimum of 8 sessions. Each patient then viewed the 25-minute film continuously on 4 occasions. After this preparation, the treatment was administered in the same manner as previously described. This modified treatment yielded a success rate of 83% (23 of 28 phobic individuals). All 23 successful patients flew after treatment, although most did so accompanied by a family member. Early follow-up data (3–18 months) on some patients suggest that they have maintained their behavioral gains.

DISCUSSION

We believe that this series of studies has demonstrated that audiovisual treatment programs designed to be administered by paraprofessionals were effective in the treatment of flight phobia. Not only was the initial outcome successful but behavioral improvement was maintained.

The major finding of the follow-up study was the differential outcomes among the behaviorally successful, attitudinally successful, and unsuccessful subjects. Eighty-two percent of the behaviorally successful subjects were able to fly $3\frac{1}{2}$–$5\frac{1}{2}$ years after treatment. The 3 cases of relapse seemed to be explained by an identifiable sensitizing experience or more general psychological factors. The unsuccessful subjects are still unable to fly, which is consistent with Marks' observation (9) that phobias are quite persistent and if untreated or unsuccessfully treated are unlikely to improve. Spontaneous recovery for this disorder is uncommon.

The inability of the attitudinally successful group to fly after treatment is difficult to interpret. It is possible that these subjects so wished to please that their self-report after treatment was inaccurate. Reliance on self-report, which could not be avoided in our program, is a common problem in outcome research. However, it is more conceivable that the subjects were accurate in their appraisal, but with the passage of time and without behavioral trial the therapeutic gains dissipated. It would seem essential, then, to include behavioral trial as part of treatment in every case.

The participants' ratings of their emotional comfort levels and the use of security items by many raises questions about the therapeutic ends achieved in this program. Although the majority of current fliers reported a positive change in their attitude toward flying and felt less anxious while flying, only a few reported themselves as "cured" and nearly half reported using security items when they fly. Thus, although the treatment helped the individuals to cope substantially with their fear of flying, flying-related anxiety did not entirely disappear. This finding parallels clinical experience suggesting that a large number of phobic patients, particularly those with multiple phobias, when treated are not "cured" even though they may be more capable of coping.

The data on generalization point to the development of coping skills and are consistent with a coping interpretation of fear reduction (e.g., Goldfried [10]); that is, subjects reported gains in areas not immediately related to flying. The subjects in our study reported feeling more relaxed in general and able to reduce tension in stressful situations by using relaxation techniques they learned during treatment and other antianxiety maneuvers. What seemed to occur for many subjects was the development of a "set" of being able to deal with anxiety that they applied in a variety of stressful situations. However, the marked positive shift on 14 of 24 experimental MMPI scales suggests generalization in other areas that we have not assessed behaviorally.

Experience gained in the use of the automated treatment by nonprofessionals allowed for a modest revision in the treatment procedure, which resulted in an improvement in treatment results compared with the procedure described in this paper. This modified treatment, which produced a more rapid and predictable result, involved more relaxation training at home and pre-exposure to the audiovisual program. However, this modified treatment was administered by experienced clinicians, and that unassessed variable must be

considered when the improved success rate is evaluated.

We are preparing another film to treat acrophobia. If the results of the study described here can be replicated, it may be possible to develop a library of audiovisual treatment programs. These might cover a wide variety of anxiety-provoking situations that can be classified under the broad umbrella of phobic and avoidance behavior and could lead to greater economy of therapist time.

The Manfred S. Guttmacher Award

The American Psychiatric Association invites applications for its annual Manfred S. Guttmacher Award for 1979. The award is given for any outstanding contribution to the literature of forensic psychiatry in the form of a book, monograph, paper, or other work, including audiovisual presentations (films, etc.), submitted to or presented at any professional meeting or published during the period from November 31, 1977, to December 1, 1978. A plaque and an honorarium of $500 will be presented to the award recipient at the Convocation of Fellows at the 1979 APA annual meeting in Chicago, Ill. Please note that the award recipient is now required to give a lecture at the annual meeting.

Anyone who wishes may apply to receive the award by submitting five copies of the work as well as five abstracts to Carl P. Malmquist, M.D., Chairman, Guttmacher Award Board, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Entries will be acknowledged but will not be returned.

The deadline for submissions is December 1, 1978, and any entry to be considered must be in Washington by that date.

Coping Styles of 34 Adolescents with Cerebral Palsy

BY KLAUS K. MINDE, M.D.

The author presents a follow-up study of 34 children with cerebral palsy. Eight years previously 23 of these children were attending a special school for handicapped children, and 11 were attending regular schools. The author evaluated the children and their families through formal and informal interviews and by administering parent and teacher rating scales of the children's behavior. He found that the development of these children between the ages of 10 and 14 was highlighted by their increased awareness and their parents' awareness of the permanence of their handicap and their consequent search for personal and, ultimately, occupational identity and their parents' emotional withdrawal.

THE INCIDENCE AND TYPES of psychological disorders associated with cerebral palsy have long been of interest (1–3). Although older studies (4–7) investigated specific difficulties encountered by handicapped individuals and their families in the course of their development, more recent work has pointed out the great complexity of social, organic, and psychological factors that influence the day-to-day functioning of the handicapped individual. For example, Richardson (8, 9) and Kleck and associates (10) measured the attitudes of different population groups toward various handicaps, and Rutter and associates (11, 12) and Shaffer (13) assessed the psychiatric morbidity of handicapped children with and without CNS disease. The latter group (11–13) consistently found physically handicapped children without brain damage to have a somewhat higher incidence of psychiatric disturbance. Cerebral palsy children with well-documented cerebral damage, however, had an even higher rate of psychiatric morbidity than healthy children.

These studies are important and may help us identify psychiatrically high-risk groups among the handicapped. They are of little use, however, for understanding the individual child and his or her family. Furthermore, most give a cross-sectional account of groups of children of various ages, ignoring the developmental aspects inherent in interpersonal relationships. For example, family conflicts, which may be the primary source of psychiatric symptomatology in primary-school-aged children, might become less important during adolescence, when children can begin to find other models of identification and have developed cognitive structures that may help them counterbalance some of the intrafamilial difficulties.

The methodological problems of measuring interactions between children and their caretakers or peers over time are obviously formidable and may account for the paucity of studies examining such processes. Kogan and associates (14) reported on 10 children with cerebral palsy under the age of 5 whom they had observed in interaction with their mothers for several years. The mothers showed a decreasing amount of warmth toward their children during the second and third year, especially if the child had not yet learned to walk. This indicated that the expectation of normalcy and the recognition that the child might not be normal was an important shaper of caretaker/child interaction. One other study (15), which did not measure actual parent/child interactions, reported on 210 children aged 4½–9 with congenital rubella 4 years after they had been initially investigated on various physiological, cognitive, and temperamental parameters. All of the children in this study had hearing defects, and 30% were also described as "neurologically damaged." The author reported that general parental concern had increased significantly between the time of initial contact and the time of follow-up (75% versus 90% of parents had an average of 2 versus 2.5 complaints) and that 79% of the children with neurological defects showed 3 or more severe behaviorally abnormal symptoms.

In summary, it appears that children with cerebral palsy and especially those with associated brain damage show a generally high incidence of behavioral difficulties. It is not clear, however, whether particular symptoms are related to specific ages of the children and to what extent general family functioning is influenced by the specific developmental tasks these children have to master. In addition, little is known about the long-term psychological development of children with cerebral palsy. In this paper I will attempt to answer some of the following questions: 1) How do children with cerebral palsy cope with the various hurdles inherent in the developmental process? 2) How do their families adjust to different developmental stages as they are modified by cerebral palsy? 3) Are children

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

in special schools better off than those in regular classrooms? 4) Does contact with nonhandicapped children at specific times enhance or protect against psychiatric disorders? 5) How do the children come to terms with their handicap?

METHOD

Subjects

The present communication is a 1975 follow-up of 34 of the 41 children with cerebral palsy admitted in 1967 and 1968 to kindergarten and first grade at the school of the Mackay Center in Montreal. At that time the school provided daytime instruction only to children who had physical handicaps severe enough to prevent them from entering a normal school and intellectual ability that was at least in the educable range. Further details concerning the school and the study population have been published elsewhere (16, 17). The present sample comprises 83% of the initial group. Of the 7 children lost, 1 had died and 6 had moved away from the area. Twenty-three of the remaining 34 children were still attending the Mackay School in 1975; 11 had been discharged and were attending regular schools.

The handicaps of the children still attending the Mackay School were severe (i.e., the children needed substantial help and could not go anywhere unaccompanied) or very severe (children needed help in all daily activities). Fifteen of these children had quadriplegia with or without hydrocephalus, 5 had severe paraplegia, and 3 had other associated congenital abnormalities.

The children who attended regular schools were moderately handicapped (5 had hemiplegias, 4 had mixed cerebral disorders and congenital abnormalities, and 2 had poliomyelitis). All of these children lived at home The two subgroups did not differ on any of the other background variables shown in table 1.

81–100	12
60–80	5

Procedure

As reported previously (16, 17), from 1967–1971 I spent 3–4 hours a week in the Mackay School meeting with school personnel, the child, and/or his or her parent to discuss the emotional and cognitive development of each youngster. In addition, each parent and child had at least one formal interview every 2 years. In 1971 I left Montreal but returned in 1973 and 1975 to conduct follow-up interviews at home and in school.

In the formal interview I obtained data about the family's current social, economic, and psychological functioning, including conflicts among parents or siblings and the handicapped child. I also assessed the status and consequences of the handicap as perceived by the parents at the time of the interview. In addition, the parents were given a symptom checklist developed by Rutter and associates (18), and teachers were interviewed and asked to fill out a similar rating scale (19) for each child. Finally, the child was interviewed alone and assessed psychiatrically using the format described by Rutter and Graham (20). The c[illegible] asked about his or her handicap and futur[illegible]

RESULTS

In the course of our extended meetings, [illegible] provided considerably more data than w[illegible] during the formal interviews. Therefore [illegible] some clinical judgments to the statistic[illegible] square analyses) when this seems warrant[illegible]

All of the results were initially analyze[illegible] for sex, type of school (Mackay School [illegible] school), and three IQ levels (see table 1[illegible] were not different between these subgroup[illegible] ed for the total sample.

Question 1: How is family functioning [illegible] the developmental hurdles of a child with [illegible] sy over time? The families of these childre[illegible] rienced few psychologically dramatic occ[illegible] ing the 8-year follow-up period. Four cou[illegible] divorced; all of these had experience[illegible] throughout their marriages. None of the [illegible] institutionalized or physically harmed a[illegible] placed in foster care. However, the[illegible] subtle changes in the attitudes expresse[illegible] ents that reflected the chronic stress to w[illegible] the families were subjected.

In 1975 fewer parents (N=14) hope[illegible] provement in the physical condition of the[illegible] had 8 years previously (N=26); this differe[illegible] nificant ($p<.02$). This may simply reflect [illegible] the children had reached their optimal d[illegible] opment and their families had adjusted to [illegible] 8 of the 14 parents who still hoped fo[illegible] changes in their children's condition sin[illegible] stated that they had seen very little imp[illegible] their youngsters' physical and school [illegible] over the past 5 years. In addition, at [illegible] tellectual performance in the whole group [illegible] remained quite stable over time (see table [illegible]

TABLE 2
Intelligence Distribution of 26 Children Tested in 1968 and 34 Children Tested in 1975*

	1968		1975	
IQ	Number	Percent	Number	Percent
101–115	4	15	8	24
81–100	18	70	17	50
60–80	4	15	9	26

*Although 41 children were studied in 1968, only 26 had received reliable test scores.

findings suggest that the objective level of the children's physical and intellectual performance was not the main factor in the parents' judgment. This idea is further supported by the statistically significant shift in the outcome predicted for the individual youngster: far more parents were quite unsure of their child's future in 1975 (35%, compared with 12% in 1968; $p<.02$).

In terms of general family discord there was little gross change over time. Six families showed much, 10 showed moderate, and 16 showed little family discord, indicating that parents who managed to survive the first 5 years of living with a handicapped child appeared to weather the following 7–8 years as well. However, far fewer parents indicated that they discussed the difficulties they had with their child with each other or with anyone else than had before (50% versus 90%, $p<.01$). For example, 7 mothers mentioned the father's continued unwillingness to think about the emotional needs of their handicapped youngster and their own subsequent withdrawal from the child in an attempt to maintain their marital relationship. Twelve couples also told of having given up their attempts to receive personal guidance and support from their physicians. Their doctors had typically been very supportive during the early years of the child's life, when they talked freely about his or her physical and cognitive growth. Once changes in this area became less obvious, however, the parents reported that their doctors refused to talk about anything beyond the child's physical disability and thus seemed to have virtually nothing to say to these parents.

Fourteen of the 19 families who had other children claimed that the nonhandicapped siblings had suffered psychologically by being deprived of attention and care, especially in the early years. In 10 instances they also described a great deal of discord between their children, with the nonhandicapped older sibling forbidding the handicapped youngster to attend his or her parties or partake in other parts of their adolescent activities. These intersibling quarrels were restricted to families whose children still attended Mackay School and therefore always involved the more severely handicapped youngsters.

Question 2: What changes took place in the interactions between the parents and the handicapped child over time? As previously indicated, the parents became less hopeful about the future of their children. This was associated with a number of other developments in parental child-rearing practices. For example, children who went to regular school were "babied" less frequently than those still attending Mackay School (18% versus 35%). Parental discipline had also changed, with nearly 50% (compared with 8%) of all families in 1975 seeing no need to punish their children anymore. Although this may be an expected development reflecting the increased self-discipline of older children, parents often described it in such a way as if to say that they had given up trying to control their child's future.

Another area in which the possibly greater emotional distance between generations came up was in the scant knowledge parents generally had about their children's perception of their handicap. In 1975 60% of all the parents had no idea of what their youngster thought about his or her handicap and stated that they never mentioned it in front of the child. They also did not discuss their child's occupational or personal future with the child and assumed that he or she never thought of it as well. Even those parents who claimed that their child realized something about his or her physical and/or mental condition often did not know what the child's exact concept was. The unhappiness often found between the generations was confirmed by the substantial frequency of verbal arguments that occurred per week between the parents and their children (up from 1.6 in 1971 to 4.8 in 1973 and 3.8 in 1975). These arguments mainly centered around the child's responsibilities in the house. The arguments in 1975 were more frequent in homes in which the children still attended Mackay School (5.1 versus 3.2, $p<.01$), indicating that the less physically disabled children could satisfy parental expectations more easily.

The concerns parents had about their children also changed over time. In 1968 the most common concern (32%) was about the child's ability to get help for his or her physical disability, and only 3% of the parents showed concern for the child's learning ability. In 1971 parents were most concerned about their child's psychological functioning (21%) and their own role in assisting the child's development (15%). From 1973 onward this changed again; general retardation and academic deterioration became the main focus of parental apprehension (33% in 1973, 47% in 1975). Although a large proportion of the retarded children (78%) gave cause for concern in this area, 36% of those who scored within the normal range of intelligence also had worried parents. In addition, such practical issues as the difficulties in transporting an older and therefore much heavier child surfaced as a main parental concern in 1975 (13%), while the future capability of the child to cope emotionally ranked last (4%).

Question 3: How do the handicapped children see their development? Although each child reacted in his or her own unique style to the task of growing up with such a severe handicap, some general developmental sequences stood out. Starting in 1971, all of the nonretarded children talked openly about their handicap

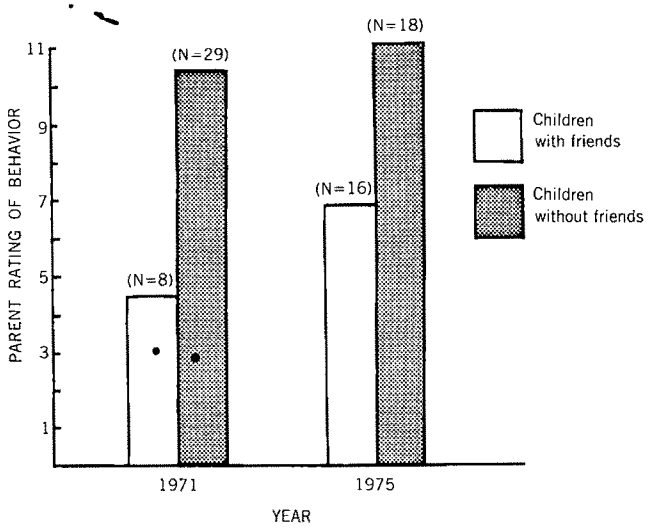
and seemed to conceptualize at least part of its consequences. Although some of them would initially say that they "had C.P.," all but 3 in 1975 could give a medical term for their handicap. The 9 retarded children also mentioned that they were not like other children, yet 6 of them still believed that they would grow out of their handicap within the next 5 years. The retarded children also either had highly unrealistic occupational expectations (e.g., a hydrocephalic quadriplegic child wanted to work for the local telephone company out in the country stripping overhead wires) or did not know what they wanted to do later (65%). Ninety-two percent of the intellectually normal group still attending Mackay School in 1975 talked about some occupational plans, although all of the children except 1 quickly added that they were "really not sure about it." The same apparent hesitation in regard to their future came out in the children's educational aims. Only 1 girl hoped to enter college, 4 retarded and 6 nonretarded youngsters thought they would finish grade 10, and the rest hoped for a high school diploma. None of the children had thought of a life beyond school.



The children who went to a regular school thought similarly about their future schooling, but 70% had specific occupational plans (e.g., secretary, nursery school teacher for handicapped children, housekeeper) that they felt confident they could achieve. Six of these children who were not retarded also imagined that they would be married some day and generally thought about their life in a more long-range perspective. A further change was seen in the type of friendships these children were able to make. As discussed in a previous paper (17), only 15% of all the children had nonhandicapped friends when they were in third grade. This figure remained stable for 2 years but improved in 1975: 36% of all of the children had regular contacts with nonhandicapped youngsters in 1975. The friendships most commonly were with children 1 or 2 years older and generally conversations and some common outings.

Question 4: What is the incidence of turbance in children with cerebral palsy tects against it? The results of the psyc ments are shown in table 3. Parent ra deviance for all groups of children dec what from 1971 to 1973 and climbed a Teacher ratings were generally lower a variation between 1971 and 1975. The ings using an interview technique (20) s crease in poor mental health over time 1975 18% of all the children were assess definite psychopathology.

The patterns of disturbance the chil were not specific but covered both co rotic disorders. However, the persistenc in individual children was quite strikin youngsters who had all 5 teacher ratings and 1975, 4 had abnormally high ratings sion, 3 on 3 or more ratings, and 8 scor abnormal range less often. Parent rati equally high consistency: 5 children were abnormal on each occasion, 4 others on a 5 on 1 rating. Approximately 40% of the dren were identified by both teachers a each of the ratings.

When possible predictors of deviant be assessed, retardation correlated with symptomatology only until the child was

FIGURE 2
Parent Ratings of Behavior of Cerebral Palsy Children With and Without Nonhandicapped Friends

grade. A return to regular school did not change the rate of deviance. Severe family discord was not associated with a consistently high parent rating of the child but correlated significantly with teacher (r=.59) and psychiatric ratings (r=.68). A significant correlation was also found between having a nonhandicapped friend and low ratings on both teacher and parent measures of deviance (see figures 1 and 2). This relationship extended to the total sample and in practice meant that fewer than 10% of the children who had a nonhandicapped friend were likely to be labeled deviant at any time during the 8-year follow-up period, but just under 50% of those without nonhandicapped friends were described as showing psychiatric symptomatology.

DISCUSSION

The material presented must be seen in its proper context. The data deal only with a small group of severely handicapped children and were obtained through semistructured interviews, making statistical evaluations difficult. However, given the scarcity of any information in this area, the investigation revealed some themes that call for further attention.

It appears that the development of this group of children between ages 10 and 14 was highlighted by the following: 1) increased cognitive realization that their handicap was permanent and that there was very little hope for future improvement, and 2) the consequent tentative search for a more final personal and occupational identity, which, however, was still very precarious and in general did not extend beyond the hope to finish school. This can be seen as a manifestation of low self-esteem and the beginning of general passivity that so often characterizes older handicapped individuals. Although this behavior may be a reaction to the emotional withdrawal of many parents from their children at this time and a reflection of parental uncertainty as to their children's future, clinically there also appeared to be other sources of insecurity.

For example, many of the children had few meaningful relationships with nonhandicapped people; instead, they lived exclusively through their equally handicapped peer group. Their siblings, especially if they were older, frequently rejected them, possibly because earlier they had felt deprived because of their handicapped siblings' demands. It may also be that both the rejection by the older siblings and the parental withdrawal of emotional investment reflect attempts by these groups to retain their own stability. It is as if in the face of a doubtful future for handicapped youngsters, too much involvement of parents and siblings in them may become potentially damaging and must be avoided. The success of parental withdrawal and rejection by siblings may be evident in the low rate of family breakdown and major discord between the parents.

Although the incidence of psychiatric disturbance in the handicapped youngsters resembles that reported by others (12, 13), the majority of these children did not remain within the deviant category for many years. This supports the latest data of Thomas and Chess (21), who reported that 65% of the children who were seen as disturbed at age 5 were markedly improved in adolescence. In our group, all 7 children who were scored as having psychiatric problems on more than three ratings either came from a disturbed family or had parents who had insisted that they were "completely normal" or "forever crippled" (17). It appears as if the attempts of these parents to solve the conflicts brought about by having a child who was "deviant" (because he or she could not walk or speak) yet also "normal" (because he or she smiled or laughed like anyone else) (1) by attempting to mould the child into one extreme category have not been helpful. In fact, the data suggest that children who were able to bridge the gap between their "deviant" and "normal" parts by associating with both handicapped and physically healthy individuals had by far the best psychiatric outcome. This did not automatically happen, however, when a child left Mackay School and went to a regular school. Although all but 1 of the children attending regular schools had nonhandicapped friends, a number of them were trying very hard to compete with their nonhandicapped peers on all possible levels. This caused a great deal of tension, was often associated with psychological difficulties, and may be similar to the competition phenomena observed by Seidel and associates (22).

In conclusion, this study shows that children with cerebral palsy continue to exhibit an increased amount of psychological difficulties in early adolescence. As others have pointed out before (23), individuals such as physicians who are traditionally seen as providers of care and advice often do not live up to the ex-

pectation that they transgress their more traditional role of assessing and treating medical conditions. This leaves many children and their families trying to work things out alone—an often difficult task. The young adolescents of this study are now entering a phase that may determine their future personal and occupational identity. Many appear to slip into an increasingly passive role toward themselves and others, possibly a reaction to their parents' emotional distancing. The consistency of this development must be determined through future studies.

TOPICAL PAPERS: Future Mental Health Care Delivery Systems

Mental Health Care Delivery Systems: Introduction

BY BENJAMIN LIPTZIN, M.D.

THE PAPERS in this section were presented at a special session of the 130th annual meeting of the American Psychiatric Association in 1977. The major purpose of the session was to bring to the attention of practitioners and policy makers the distinction between a health care financing system and a health care delivery system. The former refers to how services will be paid for, an issue that has received a great deal of publicity because of the interest in national health insurance (1–3). The latter refers to how services are organized and delivered, issues relevant to discussions of the relative merits of community mental health centers, health maintenance organizations, private practice, etc.

It is important to understand the nature of the delivery system because changes in the financing system will have intended or unintended consequences for what services are delivered to which patients in what settings. An understanding of the different components of the delivery system will put policymakers in a better position to encourage or discourage the delivery of particular services to particular populations. For example, one proposal for national health insurance would limit the number of office visits to a private practitioner but would pay for an unlimited number of visits to a community mental health center (CMHC). Although such a proposal would capitalize on the cost containment features of an organized care setting operating on a limited budget, it ignores the question of whether a community mental health center could provide high-quality intensive psychotherapy or whether the patient population treated at the CMHC would use such services.

The papers presented here were written by leading spokesmen for four major components of the system for providing services to individuals with mental disorders. These are primary health care programs (Morrill) and, within the specialty mental health sector, private psychiatric practice (Lebensohn), state mental health programs (Okin), and community mental health centers (Sharfstein). They provide a policy perspective of where we are today and where we may be in the next several years.

Policy issues that are not addressed in depth in any of the individual papers include the need to coordinate the care received in different mental health settings as well as the need to integrate mental health services with other health and human services. The patchwork of funding and organizational arrangements has made coordination and integration difficult.

From a policy analytic perspective, there is also a need for more detailed information on which patients use what services in what settings and to what effect. A first step has been taken by Regier and associates (4), who have estimated the number of individuals in treatment in different settings. Weissman and Klerman (5) have recently urged the expansion of research efforts in psychiatric epidemiology. This should include studies designed to learn what agencies or persons "untreated" individuals rely on when they experience emotional distress. The knowledge gained from health services research and psychiatric epidemiology will be essential to future planning of mental health delivery systems.

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Liptzin is Assistant Psychiatrist, McLean Hospital, 115 Mill St., Belmont, Mass. 02178, and Assistant Professor, Department of Psychiatry, Harvard Medical School.

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editor considers this material to constitute a comprehensive analysis of the topic.

The Future for Mental Health in Primary Health Care Progr

BY RICHARD G. MORRILL, M.D.

Our largely separate mental health system has developed in relationship to a health care system oriented toward specialization and solo practice. Now the health care system is moving in the direction of primary care and group and organizational practice. New forms of mental health delivery are needed to maximize the potential of these new health care programs for mental health services. The author describes these new integrated programs which bring mental health providers into the primary health care programs for direct services as well as consultation. Issues discussed include mutual roles, changes in services, the referral process, and provider relationships. The advantages of such integrated programs include decreased stigma, increased prevention through earlier detection and referral, increased family orientation, greater coordination of care, and less duplication.

PRIMARY HEALTH CARE is currently undergoing a significant revitalization in this country as a result of past overspecialization, patient dissatisfaction, rising health care costs, and new government funding priorities. At the same time there has been a continuing trend toward increasing organization in health care delivery, e.g., group practice and health maintenance organizations. The intersection of these trends is primary health care or comprehensive health care through organized ambulatory health care delivery settings. This presents important new opportunities to reverse some of the isolation and fragmentati
mental health programs have undergo

cation and an exceedingly high "no show" rate on cross-referral. Attempts at postgraduate psychiatric education for general practitioners reached very few—usually only those who were already committed. There has been little interest in the general health of patients in psychiatric clinics and mental health centers. In addition, the expressed attitudes of psychiatrists and their medical colleagues toward each other have often been derogatory.

Given the above situation, it seems that there has developed not only a fragmented system but *two* mental health care systems—one through the primary health care provider and the other through the separate private psychiatrists, CMHCs, and mental hospitals.

Part of the answer lies in working out new joint health-mental health programs by taking advantage of these new forms of ambulatory health care delivery. These include group practices, health maintenance organizations, neighborhood health centers, hospital primary care clinics, and rural health centers. The purpose of this paper is to explore joint health-mental health programming in these expanding organized forms of primary health care. Areas I will discuss include roles, types of disorders, new forms of services, the referral process, and provider relationships. Primary health care is defined as general health care that 1) exists at the point of first contact by the patient, 2) is continuing to ensure the patient's overall health, and 3) coordinates the delivery of other specialized health and social services.

THE ROLE OF MENTAL HEALTH PROVIDERS IN PRIMARY CARE SETTINGS

There seems to be a broad consensus that there is much mental health care to be done in primary health care programs and that some mental health input is thus needed. Two general approaches have developed. In the first (1) the mental health provider carries out direct or indirect consultation only. In the second (2–6) he provides consultation *and* a variety of direct mental health treatment services. The principle embodied in the first approach is that one should facilitate mental health work by the primary health care provider but not risk taking it over. The second approach is based on the supposition that many patients will never leave the primary health care program to be diagnosed or treated in a separate mental health system and therefore the two should be integrated in the ambulatory care area.

There seem to be additional benefits for mental health providers carrying out the latter approach—full service in the primary health care program. Several authors (2, 3, 5, 6) have pointed out that, given the mistrust and poor communication between the mental health provider and health providers in general, carrying out direct service in the primary health care program serves to educate, sensitize, and create a feeling of "colleagueship." This often serves to sharpen criteria for referral and remove the "mystery" of just what the mental health provider does. As the communication and mutual respect improve, the primary health care provider becomes freer to ask for consultation for some of his problem patients. Thus a patient seen as a "crock" might be perceived instead as a patient who sets up recurrent hostile dependent relationships. The semantic difference is not important. The new perception of patient needs and feelings that might be amenable to change is important.

If the mental health provider plays a full role in the primary health care program, including consultation, evaluation, and treatment, is the primary health care provider encouraged to "dump" all the patients he finds difficult, "bad," uncooperative, or "crazy"? In general, we have not found this to be the case. There are too many other factors impinging on this referral process, which will be further elaborated below.

WHO TREATS WHAT? "PROBLEMS IN LIVING" VERSUS "MENTAL DISORDER"

Certainly, there is not yet a widely recognized conceptual framework in which to apportion mental health treatment tasks, although there does seem to be a broad emerging consensus in the literature. The general turfs seem to be the "vicissitudes of everyday life" for the primary health care provider, "self realization" for religion and to a growing extent the new "human potential movement," and "pathological symptom and behavior patterns" for the mental health provider. Of course there is broad overlap between these and the problem areas listed below.

The primary care literature (7, 8) suggests that "problems in living" might better be cared for by the primary health care provider. A partial list would include helping the patient with life crises (birth, adolescent identity, marriage and divorce, loss, death, etc.), alcoholism, normal development issues, encouraging strengths, dealing with normal feeling states in health and illness (anger, guilt, depression, low self-esteem), anticipatory guidance for mothers, changing roles of women, adjustment to chronic illness, and others. This list would also include working with stable or compensated chronic psychotics. (More primary health care providers might be willing to do this if mental health backup were more readily accessible.)

The mental health provider working in an integrated setting naturally begins to see the patients with whom the primary health care provider is not trained to work or who do not respond to his intervention. This includes adults and children with serious or life-threatening disorders, the clearly psychotic, those who require long-term or specialized treatments (e.g., group or behavioral), chronic patients who need a complex variety of backup supportive services, diagnostic problems, patients who require complicated drug treatment (e.g., lithium), and others.

It might be said that if primary health care providers miss too much mental illness, mental health providers find too much. Coleman and associates (9) noted, "Pediatricians start out from the assumption of health, psychiatrists from the assumption of illness, but both may err." What then, is preferable—a false negative (labeling a chronic depression in a young woman that affects her parenting as "You're tired—take a vacation") or a false positive (labeling a culturally determined time-limited hysterical grief reaction as schizophrenia, "You're sick")? Both practitioners take the perspective of their experience. One provider has to assume the best, which serves to support patient assets, and the other has to find the illness if he is not to miss that which may be treatable. The conclusion seems to be that each approach has its purpose and can inform, educate, and improve the other if they work together.

THE SHAPE OF MENTAL HEALTH IN THE PRIMARY HEALTH CARE SETTING

What forms of mental health service are appropriate to the primary health care program? A number of programs have successfully provided evaluation and therapies, including crisis, short-term, group, family, couples, behavioral, and drug treatments. Long-term psychotherapy has depended on the resources available. There are, however, some unique aspects of a primary health care program that the mental health services can use to become more effective.

The primary health care provider typically follows patients in brief episodes over long spans of time in contrast to a separate mental health clinic, where patients are usually seen for prolonged episodes over a relatively brief span of time. Thus the separate mental health program may try to turn out a finished product because most patients are not expected to return. However, the primary health care program assumes patients *will* continue to return for health care for themselves or their families. This makes possible new treatment formats. Long-term observation and less intensive therapeutic input for a chronic problem may be more acceptable to many patients, more effective, and more efficient.

Alternatively, one might employ a "string of beads" approach. The patient may work on the same theme or conflict over a succession of interrupted crisis episodes for which he returns to the same provider to take up where he left off—a type of interrupted continuity more possible in a primary health care setting. This allows us to reach patients who cannot easily accept the traditional time scales of psychotherapy.

Other unique aspects of this setting include a wider variety of patients and problems, which tests the adaptability and flexibility of mental health staff; the diversity of "helping figures" (doctors, nurses, dietitians, and others), which allows us to structure a wider variety of therapeutic plans to reach more patients; and the ready availability of physical ... cal diagnosis and treatment, which imp... with the psychosomatic disorders.

THE REFERRAL PROCESS—A COMPL... TRANSACTION

care and the limitations on one's role to act on these. The concept of the reference group is useful in clarifying apparently contradictory changes in attitude and behavior. A physician may in the course of a day play out different roles by virtue of belonging to several different reference groups. The "we" might be "pediatricians" at 9 a.m. in the pediatrics clinic, "doctors" at 1 p.m. when negotiating with the director of nursing, or "team member" at 4 p.m. when reviewing the day's patient load with the team. His receptiveness to mental health roles and issues may vary accordingly.

In the past few years there has been tremendous interest in a new breed of doctor—the primary care physician (a specially trained internist, pediatrician, or family practitioner). Training programs are in the process of shaping new generalist identities and show a tendency to want their own mental health teachers—at times shutting out an associated department of psychiatry. The basic issues, often unspoken, are as follows: Does the presence of a psychiatrist in a primary care program undermine the generalist "yes, we can do it all" approach? Does the psychiatrist with his associated status denigrate the developing identity and pride of the young generalist trainee and his teachers? Does he represent a punitive "big brother" function? These are factors that should be worked with so that they will not subvert the promise of a new health-mental health collaboration.

One promising vehicle for productive interaction between health and mental health practitioners is an interdisciplinary team approach. These have existed mainly in training programs thus far and have been difficult to establish in the real world because of lack of real administrative autonomy or support for the team in most programs, the costs of team meeting time in terms of measurable benefits, and the relative absence of training in true settings in most health care professions.

DISCUSSION

This paper has described mental health practice within a primary health care program—the roles, services, provider relationships, and cost issues. In the primary health care programs of the future, there is an advantage to be gained in incorporating mental health programs that go beyond the traditional consultation and liaison model, which is more suitable for mental health input into medical inpatient wards. The consultant or liaison person often functions in these settings as an emissary between separate departments or clinics.

If the new primary health care settings are to maximize an integrated approach to health care, they should bring mental health providers into the primary health care programs for direct services as well as consultation (12).

The advantages of such an integrated health-mental health endeavor include 1) decreased stigma associated with mental health services and less patient resistance to referral; 2) greater family orientation of mental health services, which are shaped by the family orientation of the setting they are in; 3) increased coordination of care; 4) more effective treatment of psychosomatic illness; 5) earlier contact with the patient and family, resulting in more opportunity for preventive services through earlier detection and education; and 6) less duplication of effort and greater manpower efficiency.

To maximize these advantages, an integrated program should incorporate the following general principles, based on existing mental health programs in primary health care settings: a broad spectrum of ambulatory mental health services on site, mental health staff who work at least 60% of the time (preferably full time), delivery of mental health and health care in the same contiguous space to promote communication, some form of interdisciplinary team activity, and accountability by the mental health care program both to the primary health care program and to any sponsoring mental health organization. One might ask at this point whether increasing the primary health care provider's knowledge of and readiness to refer patients to the mental health provider is in fact desirable if it increases demand and thus reduces the apparent insurability of such services.

Increasing the availability of mental health services will necessitate increased attention to the initial evaluation of the patient and to more appropriate use of a greater variety of resources and treatment modalities. This can meet the increased demand for services and better match the service to the need, thus helping keep costs in bounds.

The mental health staff presence can also facilitate higher quality mental health services by a larger group of health care providers, thus enlarging the effective mental health manpower pool. Two studies (13, 14) have shown that mental health services may decrease utilization of health services, but further studies are needed to validate this finding.

These integrated programs can originate from different sources. One possibility is linkage with a CMHC which can deliver much of its ambulatory care through primary health care programs to expand its availability and effectiveness. If the primary care program is neighborhood-based, the decentralization enhances accessibility. The CMHC can in turn provide backup subspecialized services that are not appropriate for the primary care site, such as hospitalization, partial hospitalization, drug abuse treatment, community residences, and special services for the mentally retarded.

Integrated health-mental health programs have been slow to form, in part due to lack of leadership. The existing separate health and mental health systems are preoccupied with developing their own programs and often find integrated services not among their short-term interests or priorities. There must develop both consumer and professional leadership that sees the field of health as a whole and provides the stimulus and

accountability to integrate our fragmented systems of care.

The Future of State Mental Health Programs for the Chronic Psychiatric Patient in the Community

BY ROBERT L. OKIN, M.D.

The author explores the problems facing the chronic psychiatric patient in the community and discusses the response of federal and state governments to these problems. Errors of the past and present are delineated and corrective actions are suggested for the future. Finally, it is argued that if society is able to meet the challenge posed by the chronic psychiatric patient in the community it will simultaneously have set up mechanisms to solve the problems of other disabled and disadvantaged groups of people as well.

THE PROBLEMS of the chronic psychiatric patient in the community and the future role of the states in dealing with these problems are of critical importance for several reasons. First, the problems faced b[illegible] psychiatric patient in the community cons[illegible] lic health issue of the most enormous[illegible] Moreover, the way in which a state gra[illegible] responsibility for this group of patients [illegible] nificant implications for the way it deals [illegible] lems of other disadvantaged groups. Fi[illegible] few years have witnessed profound change[illegible] of the chronic psychiatric patient. These [illegible] continue in the future and must be unders[illegible] fessionals and citizens alike so that their [illegible] be shaped by the needs of our patients a[illegible] by extraneous, although powerful, politi[illegible] nomic considerations.

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Okin is Commissioner, Department of Mental Health, Commonwealth of Massachusetts, 160 North Washington St., Boston, Mass. 02114.

THE SITUATION OF DEINSTITUTIONA[illegible] PATIENTS

Over the last 20 years, states have dis[illegible] sands of chronic patients from their institu[illegible] is no doubt that many of these patients ha[illegible] greatly from life outside the institution. M[illegible]

0002-953X/78/0011-1355$0.45 © 1978 American Psychiatric Association

however, continue to be discharged into communities that are unprepared to accept them, are actively hostile toward them, and are certainly unable to provide them with the comprehensive range of services they require.

Many patients who had been institutionalized for years now find themselves living in low-cost rooming houses, rocking in front of television sets, and wandering the streets. The level of welfare payments, on which many chronic patients depend for their livelihood, is set so low by both the federal government and the states that they are often consigned to a life of abject poverty. In no way am I implying, however, that community life is their first brush with poverty. Poverty characterized their lives in institutions as well, but it was both less visible and, unfortunately, more readily tolerated by society because it did not directly affect the lives or property values of the ordinary citizen. Moreover, its most pernicious consequences were often masked by the pseudoprotective characteristics of institutional life. Outside the institution, however, the poverty of the disabled patient is extremely visible and often manifested in poor nutrition, substandard housing, and inadequate access to transportation, work, and medical services. In fact, it is often the effects of the patient's poverty, rather than his mental illness per se, that has become the salient feature of deinstitutionalization in those cases in which the process has miscarried. For many patients, then, the burden of poverty has been added to the burden of mental illness, resulting in multiple episodes of decompensation, reinstitutionalization, and discharge. Such is the shame of the states—individually and collectively.

Poverty is not the only problem faced by the mentally ill in the community. Resources necessary to provide aggressive outreach, aftercare, vocational rehabilitation, and extended employment have never been sufficiently forthcoming to serve the many patients being released into the community. While patients are being released from the institution at geometrically increasing rates, resources for community services are being appropriated at a rate that is barely arithmetic. Far too little money has been provided by state and federal governments to undertake the kind of radical transformation of the mental health system that the deinstitutionalization process requires if it is to amount to anything more than a mere change in the locus of care.

ECONOMIC AND BUDGETARY CONSIDERATIONS

Initially, it had been thought that massive reallocation of resources would inevitably accompany decreased state hospital utilization, thereby reducing the mental health budget or at least permitting level funding. In certain cases this was almost promised by mental health advocates in return for legislative and executive support of the deinstitutionalization process. There developed, in consequence, a strange alliance between mental health advocates and state budget directors in which both advocated a reduction in state hospital utilization, although clearly for different reasons. As with most unholy alliances, this one ultimately became unglued when it became clear that vast amounts of money were not to be immediately saved through the deinstitutionalization process. This was true for a number of reasons, outlined below.

1. State hospitals initially lost their least disabled patients to the community. These were the patients who had worked at the institution, usually without pay, in the dietary service, laundry, on the grounds, and with the nursing staff, taking care of the more disabled patients. In short, the first patients to leave the institution in large number had essentially served as an unpaid labor force, which the institution then had to replace with paid staff in order to keep its operations going. The institution was then faced with the embarrassing paradox of requiring more staff at the very time its patient census was decreasing.

2. The problems cited in item 1 were compounded by a wave of right to treatment litigation, increasingly rigorous standards of hospital certification accompanying federal financial support, and a change in the orientation of the institution from mere custody to active treatment.

The combined result of these factors was an increased need for institutional resources, not a decrease. For many patients who had been discharged into the community in the expectation that resources and services would follow them from the institution, the results of this miscalculation have been tragic.

Given the difficulties of achieving significant reallocation from a reduction in institutional census, many states have sought to close certain of their institutions. In this way, it was hoped, the monies historically tied up in the maintenance of the physical plant could be released for community services. This strategy may have made sense programmatically but has been difficult to implement politically, for the institution over the years had become the source of major revenues to the surrounding towns and an important source of employment. Legislators and town officials have opposed and will always oppose the commissioner of mental health when he attempts to close a particular institution. This opposition will be joined by employees who depend on the institution for work. The commissioner will then be forced to choose between the most disadvantaged of his patients and the most disadvantaged of his employees. Assuming he does succeed in actually closing an institution, the commissioner will find his plan for reallocation opposed by yet another force: the state budget director, who will often attempt to divert for other purposes the savings that accrue from institutional consolidation. A prior commitment from the governor and the ways and means committees must be obtained if these hard-earned savings are to be kept within the mental health system.

Although the federal government is also under financial pressure, this is in no way comparable to that of

the states. When one considers that the cost of one B-1 bomber exceeds $93 million, it becomes clear that the issue before us is not an absolute lack of resources but rather the ways in which our national resources are being spent. The future of state mental health programs will be grim indeed unless the states are able to force a radical shift in our national priorities.

CMHCS AND THE CHRONIC PATIENT

At a minimum, this will require a significant change in the direction of the CMHC program. Despite the findings that prompted the CMHC legislation in the first place, the community mental health statute has not until recently adequately focused on the needs of the chronically ill population. For example, residential services and vocational rehabilitation, both essential for the disabled patient, had not been considered until last year "essential services" within the legislation. Influenced by this, and compounded by a lack of interest in the very disabled patient among many professionals, CMHCs have often allocated only a small percentage of their resources to the chronic psychiatric patient. Although the most recent version of the CMHC statute has been modified to include a requirement that CMHCs provide services to the chronic patient, no new monies were appropriated for this purpose. In addition, the programs of many CMHCs have been organized and delivered at the level of the federally defined catchment area rather than neighborhood and town levels, so that many centers have been unable to bring to bear on their disabled population the critically needed services of natural community caregivers such as the YMCA, the clergy, and the local housing authority.

Aggravating the problem further has been the relative isolation of the state hospital system from the community mental health system. The two systems, one operated by the state and the other influenced by the federal government, have not only been virtually divorced from one another but have competed actively for resources. The future requires the integration of these systems so that the CMHC screens those patients at high risk for institutionalization, links them with their families during institutionalization, and provides or arranges a comprehensive range of human services for those who require such services after discharge.

THE FEDERAL ROLE

A discussion of federal financing and its effects on the future of state mental health programs must go beyond delineating the problems of the CMHC program, for the issue is much more complicated, as was noted by the Comptroller General of the United States in a recent report to the Congress on the subject of deinstitutionalization (1). In this very significant document, the General Accounting Office c[illegible] lack of commitment by the federal gov[illegible] needs of the chronically disabled popu[illegible] has it been difficult for disabled patients [illegible] to the resources of certain mainstream [illegible] such as the Department of Housing an[illegible] opment and the Social and Rehabilit[illegible] they have been discriminated against [illegible] the Medicare and Medicaid programs [illegible] working together are successful in re[illegible] this situation, their ability to provide [illegible] ices to their disabled patients will con[illegible] tremely limited.

No discussion of financing would be [illegible] out some reference to national health [illegible] Although often viewed as a panacea fo[illegible] problems, most NHI proposals disc[illegible] the mentally ill in general and the chron[illegible] ill in particular. In addition, national h[illegible] proposals are not complemented by a fi[illegible] nism for those social services which are [illegible] if the insured health services are to [illegible] there is no financing mechanism to ge[illegible] sues, NHI is unlikely to have a signifi[illegible] the chronic psychiatric population. M[illegible] NHI proposals are based on an individ[illegible] model. This model by itself will do little [illegible] development of the integrated system [illegible] by the most disadvantaged of our patie[illegible]

ORGANIZATION AND INTEGRATION OF SERVICES AT THE STATE LEVEL

Financing is and will continue to be [illegible] ence on the future of state mental hea[illegible] the disabled patient in the community [illegible] that go beyond financing and relate to the [illegible] of services. Indeed, it is remarkable tha[illegible] failed to appreciate the extent to which [illegible] was, for many patients, an integrated [illegible] system that provided medical, nutrition[illegible] residential, legal, and economic service[illegible] inadequately. Many states did not rec[illegible] portance of replacing this system of ser[illegible] patient had left the institution. Those st[illegible] not recognize this either felt it was not t[illegible] bility to provide or arrange for these se[illegible] not in a position to do so because of fis[illegible] regulatory obstacles, or lack of power [illegible] availability of other human services.

The provision of a range of human s[illegible] disabled client has been and will contin[illegible] difficult in the community than it is in t[illegible] In the institution the department of men[illegible] total operational control of these servi[illegible] did not have the resources to use this c[illegible] vide its clients with a decent quality of lif[illegible] munity, the department of mental health [illegible] the resources but the power, for it clear[illegible]

ational authority for the medical system, the employment situation, and the housing market. And yet some organizational entity at the state level must assume the responsibility for trying to influence these systems, even if it does not control them. In this sense, the role of the state mental health authority must shift from one of direct service to one of planning, integrating, sanctioning, monitoring, priority setting, and funding. It is the integrative role I am focusing on here, for unless the state mental health authority can influence those systems that it does not directly control, the disabled patient will not have access to the range of human services he requires.

Finally, it must be said that many states did not adequately understand the radical nature of the changes that would be necessary for community care of the disabled citizen to succeed. The problems inherent in long-term institutionalization in large, antiquated, understaffed state hospitals and state schools were so compelling that many states failed to appreciate the potential for problems in the community. It has become abundantly clear that an improvement in the quality of life for many of our clients does not occur automatically as a natural consequence of their discharge from the institution. Social isolation is possible in cities and towns as well as in institutions. Indeed, in many places such isolation, as well as outright hostility, tends to be the rule rather than the exception unless aggressive measures are taken to prevent or deal with it. A fundamental transformation of community attitudes must be accomplished by the mental health system if the lives of our clients are to be enriched by discharge from the institution. Tremendous effort must be expended if the age-old ambivalence of our society toward the mentally ill and mentally retarded is not to reassert itself. Many of the same anxieties and fears that prompted exclusion from the community in the first place remain powerful today and must be altered if the real goal of community services is to be realized. Such a change in attitudes cannot be effected primarily by staff. Only citizens and legislators providing a kind of moral leadership in their own communities can really accomplish this mission through education, persuasion, and active struggle. Unless this alteration of community attitudes is successful, our clients will feel more isolated and alone in their new neighborhoods than they did in their old institutions, despite the services which may be afforded them. If this occurs we will have failed our disabled citizens miserably. Only the form and not the substance of their problems will have been changed.

CONCLUSIONS

Clearly, the states and their legislators are facing an enormous challenge. Success in meeting this challenge will necessitate 1) an organized effort on the part of the states to influence the federal government's responsiveness to the chronic psychiatric patient, 2) an infusion of new resources, 3) a radical transformation in the pattern of financing to permit funding of the least restrictive and most normalizing types of settings and services, 4) an integration of the mental health system with other human service systems, 5) a decentralization of services to the level of the neighborhood and town, 6) a more vigorous utilization of the natural caregivers which exist only at these levels, and 7) an increased emphasis on the role of citizens and legislators, who ultimately have the greatest ability to alter community attitudes and thereby reduce the extent of the hostility which often greets the disabled patient when he returns to the community.

The nation's success in solving these problems will have vast implications for the solution of similar problems faced by other disadvantaged groups—certain elderly people, the mentally retarded, people with severe physical handicaps, and people who have been deprived by virtue of extreme poverty. If the states, their legislators, and commissioners, as well as the federal government, are able to meet the challenge posed by the chronic psychiatric patient, it is likely that they will simultaneously have set up mechanisms to solve the problems of these other groups as well.

It is not an exaggeration to say that the chronic psychiatric patient challenges not only the mental health system and the human service system of the states but the very structure of our society—its behavior, values, and beliefs. It has been said that a society can be judged by the way it treats its least fortunate members. Will the states' response to the chronic psychiatric patient stand up to such judgment?

Private Practice of Psychiatry: Future Roles

BY ZIGMOND M. LEBENSOHN, M.D.

Psychiatrists in private practice have contributed more to treating the mentally ill in America than is generally known. The private practice sector may be viewed as a massive national outpatient and inpatient service for the mentally ill. The impact of national health insurance on the future character of the private practice of psychiatry and the thorny problems to be resolved are discussed and compared with the experiences of England, the Soviet Union, and China. Future trends will most likely include increased emphasis on adjuvant techniques, greater emphasis on resident training in general psychiatry, briefer forms of therapy, and psychiatry's return to the medical model.

Alas for those that never sing
But die with all their music in them!

—Oliver Wendell Holmes, "The Voiceless"

PSYCHIATRISTS in private practice have had a singular ineptitude for telling their story. In spite of their major contributions to the efficient delivery of mental health care to a substantial segment of the population, their achievements have gone largely unsung. The reasons for this are multiple and complex. Most psychiatrists in the private sector are so swamped by their clinical responsibilities to their patients that they have little time or energy to compile statistics, write about what they are doing, or mount a campaign to quantify their results. They are characteristically a hard-working, dedicated group who devote 90% of their time to treating their patients, a task that is often exceedingly demanding. Thus they tend to be ineffective spokesmen for their cause. Possibly as a result of all these factors, psychiatrists in private practice have been called "an endangered species" by critics from both within and outside the profession, and they well may "die with all their music in them."

It was not until 1968 that the American Psychiatric Association finally recognized the need for a study of private psychiatric practice in the United States and appointed a task force to study the

HIGHLIGHTS OF THE KENTUCKY SURVEY

According to the survey of mental health needs in Kentucky conducted in 1970, the private practicing psychiatrists of that state treated approximately 12,300 people. The APA task force report concluded that private psychiatrists treated nearly one-half of all persons who received psychiatric treatment that year. The report went on to say,

> The private practice segment of the profession in Kentucky is the largest component of the state's mental health delivery system. This finding quite possibly may be applicable to the nation as a whole. . . . It is useful to picture the private practice sector of psychiatry as a massive national outpatient and inpatient service for the mentally ill, and one that meets the service needs of about half of all emotionally disturbed persons who seek professional help. (1, pp. 15, 27)

Sharfstein and associates (3) point to "the statistical hazards inherent in projecting findings from a single state to the nation as a whole . . ." and show that "more modest claims regarding the role of the private practice sector of psychiatry might be more appropriate even in the state of Kentucky. . . ." Statements in the report and the critical rejoinder by Sharfstein and coworkers point out the futility of such comparisons between the private and public sector: the situation is not an "either-or" one, and it seems clear that we must end with a viable mix of the best of both systems.

HIGHLIGHTS OF THE JIS SURVEY ON PRIVATE PRACTICE

It will not come as a surprise to most psychiatrists that the JIS survey reported that one-to-one psychotherapy is the dominant modality used by the vast majority of psychiatrists in private practice, although a substantial number occasionally combine it with adjuvant techniques such as group, conjoint, or family therapy. The use of these other techniques tends to be more widespread among child psychiatrists and general psychiatrists than it is among psychoanalysts. Marmor, in his commentary, regretted this tendency among analysts and urged greater flexibility in the psychoanalytic sector for the greater benefit of patients.

As might be expected, the added use of small-system modalities, with chemotherapy when indicated, seemed to shorten the course of treatment. With the imminence of some type of national health insurance and its understandable emphasis on the cost-benefit ratio, pressures will be exerted on psychiatry to use these less expensive methods.

The number of patient visits per year in the JIS survey appears to be significantly higher than in the Kentucky survey. The JIS survey reported an average number of psychotherapy visits per year for nonanalytic patients of only 38, and the figure was even lower for those receiving adjunctive chemotherapy. The average number of visits per year for analytic patients was 140. Although Senator Kennedy in his commentary said he was "personally convinced that this therapy (psychoanalysis) is the best medical science can offer to many patients who are in deep need of treatment," he made the shrewd observation that

> the average cost of a year's analysis (at 140 visits) today would be over $6,000. In face of this very high cost, it is distressing to note the relatively limited attention being given in private psychiatric practice to group and other treatment modalities that hold apparent promises for more efficient, less costly treatment. . . . Finally, grave problems remain with respect to equity. If we were to implement a comprehensive National Health Insurance Program tomorrow . . . we would be asking the 80% of American families whose earnings are under $20,000 a year to pay the lion's share of the cost of a health care service which is rendered by and large to individuals in families whose incomes are over $20,000 a year. Moreover, we would be asking black families to pay taxes for services only 2% of which go to blacks. And, of course, we would be asking residents of areas of the country which have few psychiatrists available to help pay the bill for other areas of our nation where help can be more easily obtained. (2, pp. 150–152)

Marmor is quite properly concerned by the double-edged nature of overfrequent sessions. Most general psychiatrists would agree that most patients treated on the average of once a week do every bit as well as those seen 3 or 4 times per week. He emphasized that it is not the frequency of therapy that is the crucial determinant but rather its *duration*. Franz Alexander's observation (4) that high frequency of sessions may be antitherapeutic and even lead to excessive dependency on the therapist has been made many times (before and since) by seasoned psychiatrists who sense this danger and take steps to wean the patient from this unrealistic type of support before it is too late.

Whether analysts would see their patients more frequently if all visits were covered by a health insurance scheme may be open to question. If they did so it might raise very serious ethical, technical, and fiscal problems. In this connection Marmor refers to some recent data collected by the late Dr. Louis Reed, compiled from the Blue Cross/Blue Shield plan for federal employees, which pays 80% of psychiatric fees above a $100 annual deductible. Reed found that in 1973 in the Washington, D.C., metropolitan area, psychiatric patients with charges of $5,000 or more for that year constituted only 3% of all persons with supplemental mental health charges but incurred 19% of the total charges for mental illness. For the United States as a whole it was found that 2% of persons (all or most of whom were presumably in analysis) accounted for 17% of the charges.

COST OF PRIVATE AND PUBLIC SERVICES

Because of the time-consuming nature of one-to-one therapy, the cost per unit of service is high, and the

patient faces a serious financial burden, especially if he is not covered by some form of insurance. This gives rise to much loose talk about high fees and fat incomes enjoyed by psychiatrists. However, the AMA reported that psychiatry ranks next to last among 8 specialties in yearly net income. Only pediatrics ranks lower.

The difficulties of making a meaningful comparison between costs of one hour's therapy by a private psychiatrist and by a psychiatrist in a CMHC were clearly presented by Sharfstein and associates (5). The JIS median cost figure for therapy by a psychiatrist was $35 an hour in 1973. Data from 53 CMHCs in 1974 indicated that the cost of one hour's psychotherapy by a psychiatrist in a CMHC "could be approximated at $45 per hour" (5). The CMHC estimates ranged from $20 to $70 an hour. Again, we see an example of the futility of comparisons between apples and oranges, which benefit no one.

ATTITUDES OF PRIVATE PSYCHIATRISTS TOWARD NATIONAL HEALTH INSURANCE

American psychiatrists have traditionally been more liberal politically than doctors in most other branches of medicine. Although no individual poll can be cited, it is my impression that most psychiatrists feel that some form of national health insurance is inevitable; most of them hope, as does their parent organization, the APA, that mental illness will have equal coverage with other illnesses under any form of NHI. Most psychiatrists of my acquaintance in private practice have a rather fatalistic attitude toward the possible advent of national health insurance. Perhaps they are lulled by the fact that most of them have full practices and their patients seem to be satisfied with their services. This may explain the results of a 1973 Harris poll which showed that even though confidence in all institutions was declining, the American public still had a higher degree of confidence in medicine as a profession than in such institutions as higher education and the military. All of this suggests that the American public trusts its own doctors and may not be as dissatisfied with the present system of medical care as is so often reported.

It is also my impression that most private practitioners would tend to agree with Eli Ginzberg's observation that

> the shortcomings and defects of the health care system are not likely to be cured by national action alone. The problems of access, availability, and quality of care are not likely to be solved through national legislation and administrative action because of the tremendous variability and the distribution of resources among and within regions and small areas of the country. The only way a national solution might work is if the entire system were under total government control—doctors, hospitals, patients. Yet even in Yugoslavia and Bulgaria, which have such systems, I have found that access, availability, and quality are a long way from being assured to the entire population. (6, p. 18)

Unless there is a radical and unforesee[illegible] democratic form of government, with i[illegible] the free enterprise system, it is unlike[illegible] care will be placed under "total gove[illegible] trol" in America. However, a quick lo[illegible] happened in other countries may give [illegible] to what the future may hold for those [illegible] tice.

EXPERIENCE IN OTHER COUNTRI[illegible]

The British National Health Service [illegible] istence since 1948. Although there hav[illegible] from time to time, most Britons wou[illegible] there to stay. Under the British syste[illegible] tice is not outlawed, and many psychi[illegible] part-time private practice in additio[illegible] tients assigned to them under the natio[illegible] Citizens who have the means to con[illegible] chiatrist are able to obtain treatment [illegible] have greater latitude in choosing a p[illegible] though this practice is periodically at[illegible] bour Party and unions on the grounds [illegible] festly unfair and that the right to good [illegible] never be affected by the power of one [illegible] private practice in Britain has continue[illegible]

In the Soviet Union I expected to f[illegible] medical care under total governmental [illegible] Ginzberg described it. However, I was [illegible] prises. On my last trip to Leningrad, [illegible] schoolteacher in her 40s who worked f[illegible] ing school vacations. Toward the end [illegible] after visiting several psychiatric inst tu[illegible] fided to me that she had consulted a ps[illegible] had benefited greatly from his help. [illegible] seen the psychiatrist at the "Dispe[illegible] trict. She replied emphatically and [illegible] "Oh, no! I see him privately at his hom[illegible]

One is reminded of an episode in [illegible] *Cancer Ward*. Dr. Lyudmila Dontsova [illegible] believed somewhat naively but fanatic[illegible] viet medical system of total governmen[illegible] when she developed symptoms of cance[illegible] became terror-stricken at the possible [illegible] and, instead of consulting her colleagues [illegible] went as a private patient to her former [illegible] Oreshchenkov, an older man, now ret[illegible] still permitted to conduct a small privat[illegible] dialogue between Dr. Dontsova, the y[illegible] state-controlled medicine, and Dr. Ores[illegible] saddened but wise old exponent of p[illegible] and personalized service, brings out the [illegible] weaknesses of both systems, with the g[illegible] model emerging as the superior and m[illegible] system of ministering to the sick.

The few reports available concerning [illegible] psychiatry in the People's Republic o[illegible] dicate that their entire health system [illegible] more rigid and total governmental contr[illegible]

case in the Soviet Union. It is doubtful, for example, that any private practice exists there today. Some observers have commented astutely that the reduction or elimination of prostitution, drug addiction, unemployment, begging, abject poverty, starvation, venereal disease, and crime, and the general improvement in public health that has occurred since the ascendancy of Chairman Mao have done more for the mental health of 800 million Chinese than the efforts of all the world's psychiatrists and mental hygiene movements put together. Perhaps so, but most of us who live in Western democracies would consider the absolute and total conformity to a monolithic political system too high a price to pay. The example of China, however, points up the truism that shapes the future form of the practice of medicine in any country—namely, that any system of medicine exists at the pleasure of the society it serves. Society giveth and society taketh away. Political systems such as ours, which permit a diversity of medical practice, may be more inefficient at times, but their great strength lies in the freedom given to the human mind to develop new and better methods to serve the sick. In this freedom lie both the warning and the challenge to the private practice of any profession, including psychiatry.

FUTURE TRENDS

It is my firm conviction that the private practice of psychiatry in the United States will not only survive but will continue to flourish. Fewer psychiatrists will be going into solo practice, probably because of its special stresses, and more psychiatrists will be entering some form of group practice. Third-party coverage for psychiatry will continue to increase both in the numbers of those covered and in the psychiatric benefits provided. This is especially true of outpatient visits to a psychiatrist's office. Most health plans, as well as NHI (when it arrives), will have limits on the number of visits per year, which number may well correspond to the average of 46 found in the JIS survey for all patients (analytic and nonanalytic). Whether the limitation is placed on the total number of visits or on the dollar value of these visits, such a step is sure to influence mightily the character of psychotherapy in America. My own feeling is that this influence, when it comes, will put psychiatrists on their mettle to develop more efficient and briefer forms of psychotherapy, which will most likely involve the greater use of adjunctive methods such as chemotherapy and group therapy. People with emotional problems will continue to seek out private psychiatrists when that is the most appropriate step to take. Peer review will exert its influence on all aspects of practice, and ways will be found to circumvent one of the serious problems attending such review, namely, the erosion of patient-doctor confidentiality. The second problem that has already emerged from peer review will be more difficult to counter. I refer to the tendency to conformity. This tendency could well stifle development of innovative treatment methods and encourage mediocrity, to the detriment of the patient's health. In spite of all these problems, psychiatrists' schedules will continue to be filled even though their income may be somewhat less; they will still be able to live comfortably while pursuing their chosen field.

Changes in Psychiatric Education

Medical schools and psychiatric residency training programs will slowly but surely begin to pay more and more attention to training residents for the general practice of psychiatry. This means placing a greater emphasis on the medical model and the biological roots of psychiatry. Gerald Klerman (8) recently listed the current hierarchy of psychiatric therapies in descending order as follows: 1) insight therapy, 2) supportive therapy, and 3) pharmacotherapy. He then added that "the degree of involvement of the profession in these three therapies is in inverse proportion to the proven evidence of their effectiveness." It is now high time that the profession, and particularly psychiatric residency training programs, recognize this important fact and revise the curriculum accordingly. I believe it is inevitable that they will do so.

Group Therapy

I anticipate a sharp increase in the use of group therapy in private practice. The indications and contraindications for this specialized approach will be sharpened and new techniques will be developed. The group therapy movement will become more solidly entrenched in American psychiatry, and some of the "far-out" methods will fade into oblivion. The reasons for the phenomenal growth of group therapy in the last decade are complex, but certainly the economics of reaching larger numbers with limited personnel is one of them. Aside from that, group therapy will continue to fill a very real need in the lives of thousands of unhappy, lonely people living in our overcrowded urban centers. For these maladjusted people who have had so much difficulty in establishing satisfying interpersonal relationships, group therapy will continue to be the treatment of choice.

Social Psychiatry Versus the Medical Model

Psychiatry, frustrated by its flirtation with sociology, will return firmly to the medical model, from which it should never have strayed. Some will choose to call it the "biopsychosocial" model, a term coined by Engel (9), which includes the biomedical, psychological, and sociological aspects of all illness. Engel points out the dangerous dogmatisms of the biomedical model when it is adhered to with fanatic singlemindedness. However, the medical model, as I use that term, is broad enough to include the psychological, social, and biological factors that may be present in any illness, and the future will see its reemergence not only in the medical school but in the private practice of general psychiatry.

Will Community Mental Health Survive in the 1980s?

BY STEVEN S. SHARFSTEIN, M.D.

There are now 675 funded community mental health centers (CMHCs), covering almost half the country. Many of these programs were funded in the social optimism of the 1960s and now face a crisis of purpose and funding. Additional requirements imposed by the 1975 amendments to the CMHC act are not matched by additional fiscal resources. Programs are graduating from the federal grant to find that other sources of funds, especially third-party insurance funds, are not replacing the lost federal dollars. There is evidence that CMHCs are changing from clinical/medical programs to social programs; the numbers of persons seeking care who have diagnosable mental illness and of psychiatrists and nurses relative to other staff are decreasing. The issue is whether CMHCs as a national program are headed for extinction or whether there will be new vitality for this program into the 1980s.

IN THE GENUS of social programs called human services, a species known as the federally funded community mental health center (CMHC) is [illegible] tinction. This is the story of that pro[illegible] and nurtured in the optimism and ab[illegible] the 1960s but coping with a precarious [illegible] the 70s, increasingly burdened by fi[illegible] and multiple levels of accountability. T[illegible] story is still in doubt. Whether the p[illegible] with a whimper, collapsing under the w[illegible] problems and changing times, or whet[illegible] ate a new vitality, producing a secon[illegible] service programs fitted for survival in [illegible] become evident in the next two years.

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

Dr. Sharfstein is Director, Division of Mental Health Service Programs, National Institute of Mental Health, 5600 Fishers Lane, Rockville, Md. 20857.

Views expressed herein are those of the author and do not necessarily reflect the opinions, official policies, or positions of the Alcohol, Drug Abuse, and Mental Health Administration or the National Institute of Mental Health.

SURVIVAL FROM 1963 TO 1977

At the time of its inception in 1963 [illegible] mental health center represented a [illegible] proach" toward meeting the mental [illegible] the community. The scope of its mis[illegible] erately writ large—a minimum of 5 c[illegible] to be made readily accessible to all [illegible] of ability to pay, a commitment to ser[illegible] munity at large as well as to troubled [illegible] the same time it was assumed tha[illegible] period of declining federal financial su[illegible] ters would generate alternative source[illegible] become self-sufficient. After the firs[illegible] significant nonfederal sources did not [illegible] period of federal support was extended [illegible] CMHC program continues to rest on [illegible] after federal "seed money" initiates a[illegible] be replaced over time with increasing [illegible]

federal support. Much of this support has come from state and local funds and service receipts for older centers, with state, local, and third-party funding being a limited source of funding for centers in the initial years of existence.

The initial expectations of the new program were very high. Its success, although variable, was on the whole evaluated as satisfactory (1, 2) It managed to survive the dark ages of the Nixon-Ford years, which attempted to phase out the program on the basis that it was "a successful demonstration" and should therefore be picked up entirely by state, local, and private resources without any federal "seed money." It was the Congress that provided the impetus for its continued survival through Public Law 94-63, which clearly stated in its preamble to Title III that

> the Congress finds that community mental health care is the most effective and humane form of care for a majority of mentally ill individuals; the federally funded community mental health centers have had a major impact on the improvement of mental health care by (a) fostering coordination and cooperation between various agencies responsible for mental health care, which in turn has resulted in a decrease in overlapping services and more efficient utilization of available resources, (b) bringing comprehensive community mental health care to all who need care within a specific geographic area regardless of ability to pay, and (c) developing a system of care which insures continuity of care for all patients and thus our national resource to which all Americans should enjoy access.

Through P.L. 94-63, Congress provided for the survival of a "Great Society" program while many others perished. However, in its enthusiasm for this species of social and medical programming Congress may have created a modern day dinosaur, a huge and complex organism that requires nutrients which, from a Darwinian perspective, far exceed the capacity of the environment to sustain its existence.

From 5 essential services the comprehensive concept was expanded to 12 essential services. In addition to the original 5 services, P.L. 94-63 now requires services for children and the elderly, for persons with alcohol and drug abuse problems, and for the "deinstitutionalized" populations through the triad of screening, follow-up, and transitional living arrangements. Congress also added a number of compliance or accountability features designed to promote the accessibility and acceptability of the services provided. Requirements regarding the governing body, quality assurance, meeting certain cultural sensitivities, using at least 2% of the budget for evaluation, complying with the provisions of the law in 1 year and converting to the 12 services in 2 years, and implementing multiple reporting systems required by the federal government impose a significant and continuing management burden on CMHCs.

Additional pressures from state and local governments and from the private sector to provide data and to meet certain standards create a situation in which the CMHC is not only expected to be all things to all people but to document that happy status regularly and in great detail to a variety of audiences.

BUDGETARY SHORTFALLS

The idealism and competence of the program-oriented "authorizing" Congressional committees is not matched by the budget-oriented "appropriating" committees. Funds were appropriated at lower levels than authorized. For 5 of the 6 grant mechanisms under P.L. 94-63, funds made available by Congress were 60% below the authorized amounts; for a sixth grant mechanism, there was no appropriation. In each funding category in 1976, the first year of experience with the new law, there was a shortfall of funds leading to an impressive backlog of approved but not funded grants. The high number of projects recommended for approval but unfunded (123) amounted to $37.3 million in fiscal year 1976. At the end of FY 1977 the approved but unpaid account amounted to $37.8 million. If General Motors had to face the same backlog of orders for automobiles it would rapidly be replaced by a competitor, or a new mode of transportation would be invented! Those centers that have gotten funds have received less than the amount necessary to sustain costly clinical care—a full range of emergency, diagnostic, treatment, and follow-up services.

As of June 1978 it is estimated that there are 675 funded CMHCs. Sixty of these are alumnae of the federal CMHC programs, i.e., programs that have graduated from all forms of federal support and have not received any additional support from P.L. 94-63. An additional 329 are still being funded through the old limited staffing program, with no P.L. 94-63 funds involved, but they were expected to comply by August 1978 with the requirement of expanding to 12 essential services and the other P.L. 94-63 requirements for accountability. Without additional funds they might become "dropouts" from the federal program. Further, there remain over 800 unfunded catchment areas in the country. Today it is no wonder that there is cynicism based on the gap between the grand expectations of the federally funded community mental health center and the reality in the community, with massive unmet needs and budget shortfalls.

SOCIAL OR MEDICAL PROGRAMS?

One potential major source of funds for CMHC survival is health insurance. However, health insurance is based on an "illness" or "medical" model and the trend in CMHCs seems to indicate a shift away from the clinical or medical approach toward a "social" model. Trend data show a shift in diagnosis from 1970 to 1974. Almost 20% of all additions to CMHCs in 1970 carried a diagnosis of depressive disorders. This category dropped to 13% in 1974. For schizophrenia the

shift from 1970 to 1974 was from 19% to 11%. During this same 5-year period diagnoses of "social maladjustments" increased from 4.6% to 20%.

Complementing this diagnostic shift is a shift away from medical practitioner staff. In 1970 there were 6.8 average full-time equivalent psychiatrists per community mental health center; in 1975, there were 4.3. The number of registered nurses decreased from 9.7 full-time equivalents per CMHC in 1970 to 8.9 in 1975. During the same period the numbers of psychologists increased from 4.9 full-time equivalents per CMHC to 8.5 and social workers from 9.1 full-time equivalents to 12.2 (3).

Even for diagnosed mental illness, there is great difficulty in obtaining third-party coverage. Extra restrictions are enforced on reimbursement for psychiatric services in the Medicare and Medicaid programs and in most private health insurance programs. There are four types of restrictions in Medicare and Medicaid. First, no CMHCs are certified as providers under Medicare, and many states exclude CMHCs from provider status under Medicaid. Second, there is great variation in the eligibility of patients even when CMHC services are covered under Medicaid. For example, many poor patients seen in a CMHC are ineligible for Medicaid because Medicaid eligibility is tied to certain welfare categories rather than income. Third, benefits are limited and are often discriminatory toward the mentally ill, e.g., the limitation on the amount Medicare will pay for outpatient psychiatric care. Fourth, reimbursement, even when available, often does not fully cover the cost of services to Medicare and Medicaid eligible patients. Therefore, CMHCs remain on the periphery of third-party financing.

Although CMHCs improve their third-party status as they get into their sixth, seventh, and eighth years, this source still represents a relatively small source of support and cannot be expected to generate the funding necessary for comprehensive services that are closely coordinated with other social and medical agencies in the community. Health insurance does not pay for the time spent on the telephone, traveling between appointments, or consulting, i.e., meeting with school personnel, the police, social agencies, and dealing effectively with multi-problem families and highly disturbed individuals. It then is up to the state to provide the necessary funds, and state mental health authorities themselves are experiencing [illegible] getary shortfalls in attempting humane and sound programs for the chronic patient.

CONCLUSIONS

If the evidence bears out the notion that the CMHC program is mutating from a clinical-model program toward a social program, what does this portend for survival? If national health insurance will be only a small portion of the total program, can the companion social insurance program [illegible] ing pieces? Given the concern today about health costs—health care approached 8% of the gross national product this year—can the federal Treasury bear the costs of the CMHC program over the next 10 to 20 years?

These are difficult questions, posed [illegible] help the CMHC program cope, adapt, and [illegible] ing federal dollars, health dollars, social dollars, and private funds. It is clear that the goals and expectations of the CMHC program must be brought into line with fiscal realities. Too much has been expected of so few with so little, and priority-setting are critical, but planning cannot substitute for adequate support and resources for the community. The CMHC program, as an integral system, publicly financed and accountable in a treatment area, oriented toward quality clinical care and prevention, is a system worth preserving. The alternative is a return to the "economics" of the isolated large state hospitals and institutions for the many and the private mental hospital and practitioner for the few.

Mental Health Care Delivery Systems: Discussion

BY BORIS M. ASTRACHAN, M.D.

THE PAPERS by Lebensohn, Okin, Sharfstein, and Morrill taken together present an overview of the treatment systems in which the work of our profession is performed. Much has been made of claims of fragmented or nonexistent delivery systems, but these papers demonstrate that within a number of different sectors, patients are receiving concerned clinical care. In all of the papers, the medical roots of psychiatry are evident and the goals of practice are emphasized: to prevent disease and disability when the knowledge base is adequate; to treat or to consult as to treatment in the face of disease or disorder; to cure when possible, to care always; and to identify disability and through the use of psychosocial interventions to restore functioning.

Psychiatry is represented as a bridging discipline, with important concerns about physical as well as mental health, and with required interaction with segments of the human services and social welfare systems. The four treatment systems clearly differ in the extent to which they encompass and/or interact with social welfare systems. To some extent, this reflects the nature of the patient population with whom each system is most concerned.

The private mental health care system revolves about the efforts of the individual practitioner. To a significant extent, changes in insurance practices have democratized access to private care. Currently services in this sector are available and used by members of the working class as well as the more affluent. An organized treatment system that integrates inpatient and outpatient activities is not required; as Lebensohn notes, the individual practitioner can provide for continuity of care. In this sector the greatest proportion of the practitioner's time is spent in providing direct clinical service.

The great strength of this system is paradoxically its most serious weakness. The usual form of practice is that of the isolated individual clinician responsible for and to his patients. Individuals with complex medical-psychiatric-social problems demand much time and assistance just to provide them with adequate entry into care. This is particularly true for those who are both fiscally deprived and psychologically disabled. These individuals are not well represented among patients in the private sector.

Okin speaks clearly for the needs of the destitute severely mentally ill. The state hospital system and those receiving services from it have often been devalued by society and their requirements neglected. Okin clearly points to our responsibility to provide for the chronically mentally disabled. He identifies not only the importance of medical and rehabilitative forms of care but also the social welfare needs of this patient population.

Within community mental health centers, clinical and social welfare goals have at times become confused. Sharfstein articulates the differing goals and processes in human services and in clinical settings and raises questions about the direction in which the CMHC movement will progress. At one point it had been hoped that combining clinical and social welfare services would in fact provide for more comprehensive care for individuals in greatest need. As Sharfstein notes, this usually has not happened within community mental health centers and too frequently the chronically ill have not been served.

Morrill identifies an important role for psychiatry in multidisciplinary group practices or in HMOs. The psychiatrist consults to other practitioners (particularly to generalists) and to other health professionals, assisting them in the management of relatively routine emotional problems and with some of the emotional complications of physical illness. The practitioner is also available to deal with the more difficult clinical cases directly. The health center serves as a locus in which medical care is emphasized but in which connections are directly available to mental health, rehabilitative, and social welfare systems.

In speaking to the future of health delivery systems, all of the authors identify the importance of fiscal considerations in defining organizational structures. As Okin notes, our patients have been discriminated against in provisions of Medicare and Medicaid and if such discrimination persists and is reified in whatever form of national health insurance is enacted, our patients will suffer and our treatment systems will be incompetent to make up for that suffering.

We do not anticipate that out of these differing systems any single monolithic one will be formed. However, legislated regulatory forces probably will increasingly insist upon better coordination of governmentally funded services. In particular, voluntary hospital, state hospital, and community mental health center services can be expected to be required to complement rather than compete with one another. To some extent, we already see general hospital services interacting with government-sponsored ones, either

Dr. Astrachan is Professor, Department of Psychiatry, Yale University School of Medicine, 34 Park St., New Haven, Conn. 06519.

directly as part of CMHCs or, increasingly, as a preferred setting for the initial hospital treatment of those with insurance coverage.

Currently, each of the described treatment systems has its own unique advantages and limitations. Each performs some aspects of patient care most efficiently. The problem for psychiatry as well as for the rest of medicine is how to stimulate organizational systems to provide excellent care for individual patients without doing injury to the necessary pluralism in our health care giving treatment system. A major dilemma that is still only poorly addressed, even in theory, is how best to coordinate multiple service needs for emotionally, financially, and educationally disadvantaged patients. The failures of total institutions are well known. They are, however, matched by our inability to assist the severely disabled with medical, rehabilitative, housing, and financial resources.

BRIEF COMMUNICATIONS

A Comparison of Depression and Physical Illness in Men and Women

BY MELVIN L. SELZER, M.D., MARIA PALUSZNY, M.D., AND ROBERT CARROLL, M.D.

A limited self-rating depression scale given to male and female factory workers indicated that subclinical depressive symptoms were correlated with visits to the factory health service for females and with absenteeism from work for males. In general, the females acknowledged more depression symptoms.

IN RECENT YEARS there has been much research on various aspects of depression. Studies on the psychology, epidemiology, sociology, and neurobiology of depression are prominent in the psychiatric and related literature. Studies of subclinical depression are less frequent. We were interested in assessing a "normal" population to determine 1) the extent of depression in such a sample, 2) the possible correlation between depression and physical illness, and 3) possible sex differences in respect to these and other variables.

METHOD

Sample

The sample consisted of blue collar workers in a small rural factory where the males and females had identical occupations and similar backgrounds. Of 200 workers asked to participate, 159 responded to the first questionnaire (84 females and 75 males). Of these, 114 also took the second test (61 females and 53 males). There was a wide age range, 16–52 years, with a mean age of 28 years. Educational levels of the subjects ranged from seventh grade to 1 year of college.

When this study was done, Dr. Selzer was Professor, Department of Psychiatry, University of Michigan Medical School, Ann Arbor, Mich., where Dr. Paluszny is Associate Professor and Dr. Carroll was a medical student. Dr. Paluszny is also Clinical Chief, Institute for the Study of Mental Retardation and Related Disabilities, University of Michigan. Dr. Selzer is now in private practice, 6967 Paseo Laredo, La Jolla, Calif. 92037.

Measurement—the SDS

The Zung Self-Rating Depression Scale (SDS) (1) was used to assess the degree of depression. The SDS has been criticized by some researchers (2), but with the following minor modifications it served our purpose. First, before the test, we gave the following specific instructions to our subjects. "Answer all questions as they apply to you. If you feel an answer should be 'none of the time,' check the space 'a little of the time'; if you feel an answer should be 'all of the time,' check 'most of the time.' " We felt these instructions would allow us to compare our data with other studies using the SDS while reducing the number of questions left unanswered. Second, we added 4 questions (items 21–24): 1) I feel sad, 2) Things I try seem to go right, 3) I usually get what I deserve, and 4) I feel I get a raw deal out of life. These items were added to elicit additional data on depressed affect and self-esteem (numbers 1 and 2, respectively) and resentment (numbers 3 and 4).

Procedure

In order to assess the relationship between depression and physical illness, we correlated the SDS with absenteeism and visits to the plant health service (categorized as visits for injury or for illness).

The SDS was administered at the factory by a medical student. There was a 38-day interval between the two testing periods. The health records for the 38-day interval and for the 38 days before the first test were checked for health-related absenteeism for visits to the plant health service. The workers were told that all responses were confidential. The testing procedure took 15 minutes and subjects were paid $1.50 for filling out the questionnaire.

RESULTS

We found that females showed more depressive symptomatology than males at both SDS rating peri-

Significant correlations ($p<.05$).

ods. On an item-by-item basis, females reported significantly more symptomatology on 9 items, whereas the males did not score significantly higher on any item.[1]

The females also showed more illness behavior, as indicated by work absences and by visits to the health service (see table 1). However, not all of these differences were significant. The most clearly significant finding was that females had more illness-related visits to the health service. Visits to the health service for injuries were slightly but nonsignificantly higher for females. Absenteeism was higher for females but the difference was significant only in the first 38-day period (before the first SDS administration).

There were interesting sex differences in correlations between depressive symptoms and illness behavior. In males, depressive symptomatology was positively correlated with absences from work in the first period. No such correlation was found for females in either period. Females did show a positive correlation between depressive symptomatology and visits to the health service for illness in both periods (see table 2).

[1]A table comparing individual test scores is available from the authors on request.

DISCUSSION

In this study the female subjects reported significantly more depressive symptoms than the male subjects in terms of total scores and scores for 9 individual items. Our data do not enable us to determine whether this represents a quantitative difference in the expression of symptoms, a greater willingness on the part of females to report their symptoms, or a difference in the ways in which the sexes view their symptoms. Some researchers cite sex as a source of heterogeneity in a meta-analysis. In a survey, Blumenthal (3) stated, "Men are expected to bear their troubles silently while women are encouraged to complain. When a woman weeps or has a headache or says she isn't feeling well, she is behaving within a culturally accepted framework, while a man who engages in the same behavior is not. It seems logical, then, that when a man makes similar complaints on a symptom checklist, such complaints are indicative of more serious problems than those of women." Blumenthal argued that it was therefore "unreasonable to compare normative scores for the two sexes." This is an important consideration in studies like ours, where the primary measures are based primarily on the individual's willingness to recognize or report his/her symptoms.

Our findings that females consistently exhibited more illness behavior than males is in accord with the conclusions of other investigators (4–6) and represents, in part, a greater readiness for self-referral. The importance of this factor has been reported elsewhere (7) and is alluded to by Blumenthal in the above quotation.

When the relationship between reported depressive symptoms and illness behavior was examined, females showed significant correlations only for one test administration and visits to the health service in the previous 38 days. Males, on the other hand, showed significant correlations for depressive symptoms and absenteeism for the same period. In all cases the manifest form of illness behavior was exhibited before the symptoms were reported on the questionnaires. Therefore, it is possible that illness behavior reflected symptomatology that had been present for several weeks or longer.

The ways in which males and females exhibit illness behavior related to their symptoms deserve special consideration. Females tended to visit the plant health service and complained of functional symptoms ("headache," "don't feel good," "feel tired"). Rarely did they complain of illness with objective findings. Social pressures in the form of taboos deny men this form of illness behavior. Therefore, it is possible that absenteeism is a form of illness behavior in men. This may account for the fact that absenteeism was the only manifestation of illness behavior significantly related to depressive symptoms in men.

Blind Ratings of Mother-Infant Interaction in Home Movies of Prepsychotic and Normal Infants

BY HENRY N. MASSIE, M.D.

Home movies of infants later diagnosed as having early childhood psychoses were compared with movies of normal control infants. A scale of attachment indicators measured mother-infant dyadic avoidance and reciprocity in the first 6 months of the infant's life. Three judges blind to diagnosis saw a general trend to dampened interaction for prepsychotic infants and their mothers. Prepsychotic and normal infants were not significantly different in touching and eye gaze behaviors, whereas mothers of prepsychotic infants exhibited less adequate eye gaze and touching than mothers of normal infants.

A SERIES OF family-made home movies of the infancy of children subsequently diagnosed as suffering from psychosis, collected by researchers studying the early natural history of childhood psychosis, serve as prospective-like data for the study of mother-infant interaction, the initial signs of illness and their development, and the constitutional qualities and neurologic symptoms of the children who later become sick. Investigators aware of the children's diagnoses have reported on 3 early cases in the series (1, 2). The intrapsychic functioning of infants and their parents drawn from their psychotherapies was correlated with the observed behavior of parents with their infants in the movies. Infancy patterns of social interaction appeared to be longitudinally incorporated into and to characterize the child's later psychotic symptomatology. A third report (3) documents the appearance of symptoms for each of the first 10 cases studied. Key findings included the relative absence of symptoms in the first 6 months and the frequency with which abnormality was heralded by the failure of the children to develop mature communication of meaning, intent, and affect through facial expression at about [illegible] Many of the prepsychotic 1-year-olds [illegible] oped an aberrant plasticity or lability of [illegible] which moods and meaning seemed to [illegible] seconds.

This report presents the final phase [illegible] ratings of 13 subject and 15 control fa[illegible] three judges, blind to diagnosis and su[illegible] of the child's life, studying the fil[illegible] months of life of the two populations. [illegible] dren, diagnosed before 6 years of age, [illegible] range of childhood psychotic diagnoses [illegible] biotic psychosis, childhood psycho[illegible] schizophrenia, and mixed forms [illegible] clusiveness results from the vague and [illegible] syncratic distinctions therapists mak[illegible] noses. Additionally, it remains to [illegible] whether the different diagnoses repres[illegible] nesses, different syndromes of one i[illegible] uum in degree of severity of one ill[illegible] movies were obtained largely through [illegible] tutions and parent group newsletters. [illegible] were obtained "for a study of child[illegible] largely through nonpsychiatric instit[illegible] letters. Groups were matched for num[illegible] second-born children.

METHOD

The study of index and control cases [illegible] key modalities of mother-infant recipr[illegible] in the first 6 months of the infant's life—[illegible] ing, eye gaze, and touching (vocaliz[illegible] since the family movies were silent). [illegible] analysis these modalities were broken [illegible] ponent behaviors that I incorporated [illegible] attachment indicators used by the jud[illegible] grades the intensity of the mother's or [illegible] ment to the other from a low value of [illegible] maternal or infant aversion and isolatio[illegible] ue of 5 (indicative of intense responsive[illegible] ing). The purpose of the scale was to [illegible] tifying and verifying my impression [illegible] more maternal avoidance of attachme[illegible] and more infant apathy in the prepsy[illegible] one or more modalities than in the co[illegible]

Three judges, who were educati[illegible]

health professionals, were trained for approximately 5 hours in the use of the scale. The judge was asked to study each scene in which mother and child engaged in holding, eye gaze, touching, or feeding and was encouraged to view the scene with single frame and slow motion speeds as often as necessary to select the numbered scale description that most closely reflected the behavior occurring in the scene.

Although the judges knew about the research hypotheses and that they would be given unedited movies of the infancies of normal and psychotic children, they did not know from which group a given film came. Films were coded and chosen randomly for each judge, who then viewed the films independently. All three judges saw all of the films. After they rated all the scenes in a case, the judges were asked to make an overall assessment of mother and child. They were asked to report their general clinical impressions, i.e., whether the infant and mother seemed "unusual," "healthy," "attached or avoiding," "content," or "distressed." Fathers generally appeared too infrequently in films to permit rating. The cutoff point of 6 months was chosen because no recognizable symptoms of psychosis or autism appeared in any case before 6 months of age and also because of the fundamental importance of the first 6 months for later development.

RESULTS

Differences in Intensity of Reciprocal Responsiveness

Nonblind study led to the hypothesis that normal mothers and infants should show higher mean ratings on the scale of attachment indicators and for the judges' general clinical impressions than the prepsychotic cases. T tests were performed to determine whether the observed differences between means were significant. One-tailed tests of significance were used with t values significant at $p<.05$.

Mean ratings were determined by averaging ratings made by each judge after he or she looked at all the scenes of a given attachment behavior (e.g., feeding, holding, etc.) for each index and control case. Thus, there were three average ratings (one per judge) for each case, from which a mean score was determined. In some cases, the judges felt that they did not have sufficient footage to make a clinical rating, so the actual number of cases used to determine mean scores was sometimes different from the total number of control and index cases.

As table 1 indicates, the overall ratings show that in each of the categories—feeding, holding, eye gaze, and touching—the trend went in the predicted direction. The normal groups of infants and mothers achieved higher values for attachment than the mothers or infants in the prepsychotic groups. When t tests were used to compare normal infants with prepsychotic infants, there was no significant difference between groups in feeding behavior, eye gaze, or touching. However, infants in the normal group showed significantly higher ratings for holding ($p<.05$) than infants in the prepsychotic group.

For the two groups of mothers, there was no significant difference in ratings for feeding. However, mothers of normal infants achieved significantly higher ratings for holding ($p=.05$), touching ($p<.05$), and eye gaze ($p<.01$). Thus, in two categories—eye gaze and touching—the two groups of infants were not distinguished, whereas the mothers of normal infants were distinguished by higher ratings than mothers of prepsychotic infants, and in one category—feeding—neither mothers nor children in the two groups were distinguished.

With respect to interrater reliability, one judge had to be replaced in the middle of the project; however, each case still received three ratings. The average of interrater correlations across attachment modalities ranged from .54 to .39. When the ratings of the two judges who rated the most cases ($r=.49$) were used to complete the same t tests separately for each of these two judges' ratings, both the trends and significance levels of the overall results of the pooled data were replicated.

General Impressions of Attachment

For the global impression of each mother and child, the three judges responded to a series of questions (e.g., "Does this mother/child seem healthy . . . strongly attached . . . avoiding . . . content . . . distressed?"). Without knowing the identity of the cases I sorted the responses into three categories that were weighted numerically: 1=negative responses (e.g., avoiding, not healthy); 2=neutral responses (e.g., healthy, content); and 3=strongly positive responses (e.g., strongly attached). The values for each case were averaged. A mean of 2 to 3 was considered indicative of normal attachment, a mean of 1 to 1.667 was considered poor attachment. Each mother and child in the normal and prepsychotic groups was assigned to cells representing poor attachment and healthy attachment. Of the normal infants 4 appeared poorly attached and 11 normally attached; of the prepsychotic infants 7 appeared poorly attached and 6 normally attached. A chi-square test with Yates correction for small numbers applied to these figures indicated no significant difference between the overall impressions of the two groups of infants. With regard to the mothers, however, 10 mothers of prepsychotic infants appeared poorly attached to their infants and 3 normally attached; in the control group only 2 mothers appeared poorly attached and 13 normally attached. This distribution was significantly different from chance ($p<.01$). The correlations for the general clinical impressions for pairs of judges ranged from .67 (the largest number of cases seen by a pair of judges) to .31 (the fewest number of cases seen by a pair of judges). The overall average correlation for the pairs of judges was .47.

TABLE 1
Ratings of Attachment Behaviors in Normal (Control) and Prepsychotic (Index) Infants and Their Mothers*

	Feeding				Holding				Eye Gaze				Touch			
Group	N	Mean	SD	t	N	Mean	SD	t	N	Mean	SD	t	N	Mean		
Infant	18				27				23				18			
Control	11	3.44	.637	1.362	15	2.67	.529	1.876**	12	2.79	.862	.420	10	2.84

DISCUSSION

Unlike many investigations, this study does not use a standardized sample to which a standardized test can be applied. Rather, the home movies that families took during the infancies of their children for their own use are a naturalistic sample of family life. The typical movie scenes (bathing, feeding, holding, etc.) reappear often, although the length and detail of segments vary. There was no attempt to standardize the film segments for the judges in order to avoid biasing the samples through investigation selectivity. I also decided to limit their training to avoid influencing the judges too strongly, which would have created an experimental bias. Consequently, one judge might begin examining a given scene at an earlier point of interaction than another judge, or one judge might omit a scene because he felt it lasted too few seconds to provide an impression. These contingencies explain the relatively low interjudge correlations. If training were extended, if raters were more homogeneous, or if the film samples were more standardized, higher correlations would be anticipated.

Several important findings emerge. For all modalities of infant and maternal behavior there is a trend to lower ratings in the psychotic groups compared with the normal groups. This achieves statistical significance for infants and mothers for holding and also for the mothers for eye gaze and touching. These lower ratings suggest several phenomena in the first 6 months of the infant's life: a dampening of mother-infant interaction in dyads where psychosis eventuates in the child; less attachment of mother to infant and infant to mother in the prepsychotic group; and more avoidance and less reciprocity in interactions in the prepsychotic group when compared with normal mothers and infants. In the series of cases as a whole, the ratings do not distinguish between dampening, decreased attachment, reciprocity and synchronicity, and avoidance and isolation. However, whenever any of these dampening phenomena occur, clinical experience and psychoanalytic and attachment theory predict that the infant is likely to develop pathology.

The most striking finding is that for eye gaze and touching there was no significant differ[illegible] psychotic infants when compared to [illegible] However, the mothers of the prepsyc[illegible] ther initiated less activity with or respo[illegible] avoided more) their infants in these [illegible] suggests that as a group the prepsycho[illegible] ceived a different and less positive 'sin[illegible] than the normal infants, but does not ne[illegible] that this different mothering caused the [illegible] data are consistent with the possibili[illegible] ferent parental behavior may have facil[illegible] gence of psychosis in a constitutional [illegible] infant. Further, one cannot distinguish w[illegible] tial dampened maternal responsiveness [illegible] arisen because a primary apathy in an inf[illegible] mother's responsiveness or whether [illegible] mother profoundly affected a neonate's [illegible]

The results of the general impression[illegible] size the findings of the scale of attachm[illegible] by showing even more notably inadequa[illegible] in the mothers of prepsychotic infants [illegible] mothers ($p<.01$) and no significant differ[illegible] groups of infants.

It is interesting that feeding differ[illegible] emerge for the two groups, since psych[illegible] ry has traditionally focused on the ora[illegible] nal development. These data point to [illegible] gaze and bodily touching as two modal[illegible] aversion and unresponsiveness may oc[illegible] quently and be more crucially traumatic [illegible] feeding interferences. This, of course, d[illegible] the developmental principle that under[illegible] bidinal phase (5, 6)—that the infant's he[illegible] of organismic tension, which is initially e[illegible] a primitive life and death anxiety, must [illegible] that the infant can gradually incorporat[illegible] and ultimately identify with a mother w[illegible] enced as primarily gratifying. Rather, [illegible] phasis, as Bowlby (7) has also done in [illegible] attachment, away from a more unitary co[illegible] ity to a group of behaviors—babbling, [illegible] closeness), eating, and especially eye ga[illegible] ing. Reciprocally, the mother can frustra[illegible] mate the infant's attempts for gratificat[illegible]

these attachment modalities that are instinctually determined for both mother and baby.

The limitation of statistics is that many of the particular findings become "washed out" in looking at the whole series of cases. Individual cases (1, 2) showed how in one family a mother primarily avoided eye gaze, in another family a mother avoided ventral-ventral holding, in several cases parents initiated intense overstimulation across several modalities, interfering with the infant's ability to consummate any attachment behavior, and in other cases the infants were unresponsive to their mothers across several modalities. Patterns emerged in which children were isolated (by dint of parents avoiding them in specific ways such as gaze aversion or of the infant's own apathy) or overstimulated. The overstimulated children were effectively isolated emotionally since their parents were not able to perceive their affective distress and empathize with them. Individual case studies showed clearly that infants in the first 6 months of life had a range of affect that occurred in response to interactions with people and events in their lives, especially their mothers. The babies were not just organisms devoid of an emotional life. The mothers and fathers stimulated babies repeatedly in the first 6 months to expressions of pleasure, distress, depression, and dejection with positive parental actions or parental withdrawal and prohibitions.

Finally, the standard deviations of the ratings of both the scale of attachment indicators and the general clinical impressions reveal that there is considerable overlap between both groups of infants and both groups of mothers. This is consistent with the nonblind examination of the movies. There were gray areas in which some of the control and index group mothers and children looked similar and some in which control group mothers and children looked worse than index families. The extremes, however, were very dissimilar; i.e., the worst parental isolation, overstimulation, and avoidance and the most atonic infants appeared in the index group while the most empathic parenting and the most lively and responsive infants appeared in the control group.

In sum, the use of home movies cannot discern specific patterns of mother-infant coupling in particular cases as can be done in intensive prospective and retrospective individual case studies (1, 2, 8, 9). On the other hand, such case studies lack adequate blind controls. The controlled data from this research support the results of others and point to multiple and multidetermined etiologies for childhood psychosis.

Psychological Factors in Susceptibility to Drug-Induced Extrapyramidal Symptoms

BY PERITZ LEVINSON, M.D., RICHARD MALEN, M.D., GEORGE HOGBEN, M.D., AND HARRY SMITH, PH.D.

In an effort to identify nonneurobiologic factors in the susceptibility to neuroleptic-induced extrapyramidal symptoms (EPS), the EPS response in 20 patients was correlated with field dependence, self-object differentiation, and premorbid social competence. Only the last proved to be a good predictor, which suggests that psychosocial factors play a role in a patient's EPS response.

AT THE SAME time that use of neuroleptic drugs has greatly increased, there has been a recent and intense interest in extrapyramidal symptoms (EPS), which include parkinsonism, acute dyskinesia, akathisia, and tardive dyskinesia. Clinicians have noted differences in individual susceptibility to extrapyramidal effects of antipsychotic drugs (1, 2). Because it has been noted that the greater the extrapyramidal response to a drug the greater the antipsychotic effect (3), researchers are looking for efficacious drugs without these motoric side effects (4). The minimum research done on individual susceptibility to EPS has been almost entirely neurobiologic (5). In this paper, we will report on our investigation of the possible nonneurobiologic variables in the susceptibility to neuroleptic-induced EPS.

Psychosocial factors contributing to the extrapyramidal response have been suggested by Klein (6), who found that chlorpromazine had a consistent positive effect in reducing psychopathology among premorbidly non-asocial subjects. For the premorbid asocial schizophrenics the results were not as good, possibly because of an extrapyramidal effect. Two psychological factors that have been found to correlate with premorbid social status are field dependence (7) and degree of self-object differentiation (8). Premorbid asocial subjects have been found to be field dependent and to perceive others in a less differentiated way. We decided to investigate the correlation of the extrapyramidal response with these three personality variables—premorbid social competence, field dependence, and self-object differentiation.

Dr. Levinson is Assistant Clinical Professor of Psychiatry, Dr. Malen is Clinical Instructor of Psychiatry, Dr. Hogben is Assistant Professor of Psychiatry, and Dr. Smith is Professor of Biostatistics, Mt. Sinai School of Medicine, New York, N.Y. Address reprint requests to Dr. Levinson at 120 East 89th St., New York, N.Y. 10028.

METHOD

Twenty-six consecutively hospita[illegible] treated with chlorpromazine were stud[illegible] hered to the treatment regime. They w[illegible] 55 years of age (mean=30.5±1.89), sch[illegible] cording to the New Haven Checklist (9[illegible] antipsychotic drugs on admission to th[illegible] formed consent was obtained after the [illegible] procedure had been fully explained to [illegible] Chlorpromazine blood levels at the time [illegible] ruled out the presence of drug. At the t[illegible] sion to the project a score on the Adj[illegible] Scale (ARS) (10) for self-object differe[illegible] Embedded Figures Test (EFT) (11) fo[illegible] dence, and the Phillips Scale (PS) (12) i[illegible] social competence was obtained for each [illegible] ing a state of sufficient lucidity. The patie[illegible] started on a schedule of gradually increa[illegible] chlorpromazine. Although the dosage sc[illegible] not be absolutely fixed because of indiv[illegible] needs, there was a strong consistency in [illegible] administration from individual to individ[illegible] ment of drug side effects as well as the [illegible] quirements for sedation on an as-needed [illegible] done through the use of medications tha[illegible] crease the amounts of tranquilizer or supp[illegible] log of the daily dose of chlorpromazine [illegible] each patient throughout the project (r[illegible] mg/day).

The EPS were measured from the onse[illegible] tion via the Bordeleau EPS scale (13) [illegible] week at regular times in the day by the s[illegible] er, who was blind to medication dosage, [illegible] ophrenia, etc. At the end of the project (s[illegible] 4 weeks) the ARS and EFT were repeated [illegible] value (Δ=change in the score) for each [illegible] Greater differentiation is manifested on t[illegible] higher score and on the delta ARS by a g[illegible] value. Greater differentiation on the E[illegible] smaller score and on the delta EFT a l[illegible] value. On the Phillips Scale, the higher t[illegible] poorer the premorbid status.

The data were used for the following pr[illegible] tives: 1) Can psychosocial or psychologic[illegible] data be used to predict the number of EP[illegible] tion of increasing dosage levels during th[illegible] chlorpromazine regimen? If so, which ad[illegible]

0002-953X/78/0011-1375$0.35 © 1978 American Psychiatric Association

able is most useful in prediction? 2) Is the relative rate of increase in the number of EPS through this treatment regimen predictable by one or more of the admission variables? If so, which admission variable is most correlated with this rate of increase?

The response of each individual to chlorpromazine was assessed using two main statistics for each patient—the average number of EPS and the relative rate of increase in EPS per unit dosage of chlorpromazine. These values were determined by plotting dosage against EPS, fitting a straight line, and deriving a value for this line.

RESULTS

Of the three principal variables, premorbid social competence as measured by the Phillips Scale (12.4±1.94) turned out to be a good predictor of the relative increase in EPS per unit dosage of chlorpromazine ($r=.6481$, $p<.01$). In other words, premorbid asocial schizophrenics had a greater value increase in EPS per unit dosage of chlorpromazine and thereby demonstrated increased susceptibility to these drug-induced motor phenomena.

The negative findings indicated that age, sex, severity of illness (as measured by the New Haven Checklist) and chronicity of illness (as measured by previous hospital admissions) did not correlate well with EPS response in these subjects. Field dependence as determined by the Embedded Figures Test (pretrial=113.02±12.83; posttrial (Δ)=5.73±6.15) also showed little relationship to intensity of EPS. The degree of self-object differentiation as measured by the Adjective Rating Scale (pretrial=10.05±2.02; posttrial (Δ)=−1.85±0.96) showed no demonstrable relationship to the EPS response.

DISCUSSION

Premorbid social status was found to correlate with EPS susceptibility in our group of subjects. However, the fact that field dependence and self-object differentiation did not correlate with EPS response weakens the support for psychological causology and suggests that premorbid adjustment consists of diverse dimensions, which have been recently conceptualized as "bio-psycho-social" in nature (14).

Many physiologic as well as other psychological factors have been advanced to differentiate the good-poor premorbid dimension, but the results have been ambiguous and inconsistent (15). Central nervous system organicity has also been studied, but to date no clear relationship between this factor and premorbid adjustment has emerged (16). A possible exception may be a recent study that found "a group of schizophrenics with premorbid asociality" to have neurologic soft signs (17), but this needs confirmation. Even if the EPS-premorbid status correlation turns out to be due to the psychosocial factor, the epiphenomenal nature of this category must be dealt with. At this point, further research into the nature of the premorbid process is needed. Crucial to success in this area is the development of a standard basic premorbid scale that could be readily "plugged in" to all kinds of biological as well as psychosocial clinical research.

Psychological mechanisms have long been used to explain disorders of movement (e.g., catatonia and conversion hysteria). Muscle tone, body type, and personality type have been correlated with specific EPS responses (18). Nonetheless, at this point in our knowledge, the positive findings in this study may be taken simply as a suggestion that psychological and psychosocial factors may play a significant role in a patient's EPS response.

Psychological Observations of Bank Robbery

BY DONALD A. JOHNSTON, M.D.

Bank robbery has been only partially examined in the psychiatric literature. It has been publicly considered an act of men of strong will to obtain money. According to the author's observations in a federal penitentiary, bank robbery more often is a symptomatic act with psychological meaning. The author describes several of the unconscious motives and defense aspects of bank robbery in the hope that this will assist in demythologizing the bank robber.

BANK ROBBERIES receive a great deal of publicity. The focus of attention of this publicity is rarely on the criminal's motivation. We hear many details of how the robbery was committed, but the why is often left to "Sutton's law." (When asked why he robbed banks, Willie Sutton replied, "That's where the money is.") The assumption is that bank robbery is an attempt to get rich, or at least to get enough to live on for a while.

I shared these assumptions until 1968, when I was assigned to a federal penitentiary for men in Springfield, Mo., and interviewed many bank robbers. My earlier assumptions and the general public's fantasies about bank robbers were echoed by the inmate population. On the inside, much of the inmate's status is gained from his "criminal occupation." In federal prison bank robbers are up near the top; they are perceived as powerful and daring operators. This occurs despite the fact that in closer relationships within the walls many individual bank robbers are regarded as "punks" or "dummies." A curious split exists—a man might be regarded from a distance as impressive because he has robbed a bank, but on examination he often turns out to be passive and dependent, sometimes ignorant, often physically unattractive, and not infrequently grossly psychotic.

Certain ideas or myths that exist about the bank robber's character and actions came down to us from the 1930s, the era of John Dillinger, Alvin Karpas, Ma Barker, and Bonnie Parker and Clyde Barrow (1). These ideas are promulgated today by movie and television scripts and the drama of news accounts—a shrewd protagonist who fails to remember a significant detail of his plan is captured under fr[illegible] stances, or a vicious criminal blazes his [illegible] of a bank. There are many subplots a[illegible] most of these scripts involve a cunni[illegible] character who wants the money and is [illegible] the known hazards of security devices. [illegible] a high arrest-and-conviction rate, and [illegible] prison sentences (usually 25 years).

As my understanding of bank robb[illegible] crimes became clearer over the two yea[illegible] at the penitentiary I saw that the act of [illegible] bank robbery often had very little, if an[illegible] to the theft of money for personal profit [illegible] lieve that the bank can become an are[illegible] chological pressures are expressed a[illegible] densed action. At times the direct acting [illegible] occurs, while in other instances the robb[illegible] defense against other more overwhelmin[illegible] bing a bank becomes the lesser of two i[illegible]

Homosexuality and narcissistic issue[illegible] tence and inadequacy are particularly [illegible] bank robbery. In some instances the re[illegible] rect attempt to be killed or a self-destruc[illegible] venge. It can be the acting out of tremen[illegible] placed from earlier experiences or the gr[illegible] the wish for sadistic excitement. The imp[illegible] bank robbery is remarkable. In 1967, fe[illegible] 2,200 bank robberies, only 453 were c[illegible] men who knew anything at all about the [illegible] tion of their target bank (2).

I would like to present some of the case[illegible] these observations have been drawn. I [illegible] them into the two broad categories of the [illegible] drives and the defense against drives, [illegible] certainly many overlapping themes.

ACTED-OUT IMPULSES

Case 1. The most vivid of the cases involv[illegible] the impulse to suicide was that of Mr. A, a 44-[illegible] erately successful, self-employed attorney. A[illegible] Catholic, Mr. A considered himself very de[illegible] wife and nine children. He had been having a [illegible] ual affair: he no longer loved his wife, could n[illegible] and feared his affair was about to be found ou[illegible] came depressed and then later feared that Co[illegible] infiltrating the government. Bent on exposing [illegible] wrote long, vague, paranoid letters to newspap[illegible]

On the morning of the bank robbery Mr. A [illegible]

Dr. Johnston is Assistant Clinical Professor of Psychiatry, University of Colorado Medical Center, 4200 East Ninth Ave., Denver, Colo. 80262.

that something drastic was about to happen. He went to a bank where he was well known and robbed it with a threat backed by an unloaded 45-caliber automatic pistol. After getting the money he lingered several minutes, allowing for the arrival of the police. He aimed his gun at the police and was shot in the arm. He again threatened to fire and was once more wounded in the arm. He then ran and was finally shot in the leg and captured.

After arrest and medical treatment for his wounds Mr. A was sent to the Springfield facility for a sanity evaluation. He was significantly depressed. Of the bank robbery he said, "It seemed like I wanted to get myself bumped off." He stated that suicide was impossible for him because it would nullify his insurance. Further, as a devout Catholic he said he could not commit such an act.

Case 2. In this case there was a strong need to defend against feelings of inadequacy as well as the wish to be killed. Mr. B was the son of a successful physician father and a doting, protective mother. He felt that his father considered him a weakling. He had obtained a degree in journalism, married a greedy and demeaning woman, and was divorced by her after 7 years. He said her tombstone should read, "She wanted more." He felt he could not satisfy her in any way. Following the divorce he became depressed and felt that if he could write a book he would feel better. He was unsuccessful in this desire to write and attempted suicide by ingesting pills.

After a brief hospitalization Mr. B took a bus trip to San Francisco. He had no money with him. In San Francisco he walked the streets looking at the impressive hotels and restaurants where he had been in the past, using his father's money. He walked to the ocean, looked at Alcatraz, and considered suicide by drowning. However, he said, he "did not have the guts."

In front of a bank he met a hippie who asked him for a quarter. This stimulated a resurgence of his sense of failure because he realized he had no money. He told the hippie, "Wait a minute, I'll get some" and immediately headed into the bank. The hippie realized what was about to happen and ran away.

Mr. B saw an armed guard inside the bank, but this did not serve as a deterrent. He got in line at the teller's window and waited. When it was his turn, he attempted to rob the teller with what he described as a "Humphrey Bogart sneer" and his finger in his pocket suggesting that he had a weapon. He heard a click, turned around, and saw the guard's cocked pistol next to his face. He remembered feeling that it was "the biggest thing I had ever seen in my life." At that point, he said, "the fight went out of me," and he nearly fainted. He was convicted of bank robbery and sentenced to a federal penitentiary. He was a very quiet, well-mannered inmate who was aloof to other prisoners.

Case 3. In this case the wish for revenge was prominent. Although the robber exposed himself to risk, the real target of his aggression was his wife. His actions illustrate the dynamics of "victory through defeat." Mr. C was 51 years old, obese, and had ill-fitting dentures. He felt he was a failure financially, socially, and sexually. He had had two marriages to the same woman and had never had any children. Mr. C's wife controlled him and ordered him about constantly. Since it was difficult for him to be directly angry at her, he said he would "fiddle with chemicals in the basement making small explosions which would frighten her." When he became angry enough to threaten divorce, she would put a stop on his checking account. In 1957, in a fit of rage at her, he robbed a neighborhood branch bank with a jar of Wesson Oil. He told the teller it was nitroglycerin. He was well known at the bank and was readily identified, captured, and convicted. His wife was ashamed of him, lost community status by his action, and divorced him.

Eight years later he was released from prison, remarried his wife, and, in 18 months, did it again—the same bank, the same teller's cage, and another jar of Wesson Oil. This time he wore a dashing Tyrolean hat and a very loud plaid sports coat. He was easily recognized on the second try as "the guy who did it before." He was arrested the next day and claimed total amnesia. He kept protesting, "How could I have done it; only a fool would have done it again." He was captured wearing the same clothes he wore in the bank, where he had been clearly photographed by the automatic cameras. In prison he spoke of his act with real pleasure, knowing that he had made his wife miserable again.

Case 4. This man felt driven to avenge his childhood. His robberies were a repetition of displaced anger from early loss of a parent and probably also represented an identification with his father. Mr. D's mother had died in an Army hospital during his childhood, and he blamed the government doctors for "murdering her." By the time he reached his 20s he had evolved a delusional system in which he saw himself as a god. He committed five bank robberies in 2 years, all in the Robin Hood tradition. He would rob the bank and then go immediately to the slums of the city and distribute all the money to skid-row derelicts. He said, "It was terrific to be able to do that." To him it represented giving something important to someone in need. He also believed that the money was really "government money" and that by reclaiming and redistributing it he was doing good deeds for the poor and downtrodden. Perhaps this represented his wish to undo the loss of his mother. The giving away of money to the unfortunate was also a link to his father, who had always given small change to bums, saying, "It's a goddamned shame there are guys like that."

After disposing of all the robbery money Mr. D washed dishes until he saved enough money for an airplane ticket to the next city in Ohio, where he repeated the same acts. The cities of his robberies formed a circle around his father's residence. He never used a weapon, although he threatened bank tellers with the implication that he had one; he believed he would never be shot or harmed during the robberies because "you shouldn't be hurt while doing good deeds." He felt that bystanders in the street were cheering him on while he escaped from the banks.

Case 5. Mr. E's case illustrates how bank robbery discharged sadistic excitement. He was a small, plump, belligerent, 28-year-old from rural Georgia who had been raised in an orphanage. He was a sadomasochistic homosexual. "I like," he said, "to screw boys in the ass and bite them." He also liked "for boys to bite me before sex. If you don't have pain, you don't get anything out of it." He disliked women and enjoyed frightening them. A bank with women tellers and customers became a setting for his acting out. On the day of the robbery he took one of his young male lovers with him into the bank and screamed, "All right, this is it!" and emptied an automatic pistol across the ceiling. The noise, chaos, and terror of the women was transiently gratifying. He was apprehended before leaving the bank. In prison he said of his crime, "I was going to be somebody. It was fun and they would know my name."

DEFENSES AGAINST DRIVES

The following three cases fall under the general heading of defenses against drives. They are typical of many similar instances in which deviant sexuality or feelings of failure and inadequacy were significant features of bank robbery motivation.

Case 6. At age 31, Mr. F, a single man, robbed two banks in 3 days. He was employed as a machinist and had no previous criminal history. Several days before the robberies, Mr. F underwent an acute psychotic decompensation with referential thinking and feeling sexually stimulated. He had the delusion that his brother's posture in the machine shop where they both worked indicated they should have homosexual intercourse. He began to receive messages from television sets, restaurant waiters, and police officers that he should rob a bank.

Feeling it was "something I must do," Mr. F walked into a suburban branch bank with a note stating he had a weapon. He had never seen the bank before; he selected it because it was on a street that began with an O, and a woman he knew had a name that began with O. He hid the $1,300 proceeds of the robbery in his apartment. Two days afterward he felt driven to commit a second robbery and was arrested in the bank.

The youngest of six children, Mr. F had been raised in a middle-class family in South America. He was close to his religious mother and was treated as the baby of the family. At age 10 he began hearing voices that intermittently told him how to act. His sexual identity was tenuous. As an adolescent he compulsively masturbated and left his ejaculate in the hope it would be discovered by his mother or sisters so "they would know I was a man." His rare heterosexual experiences had been with prostitutes in meetings arranged by men who felt he should lose his virginity. Adult sexual gratification was through occasional but extremely conflicted homosexual encounters. Mr. F said that his bank robberies were "the most masculine thing in my life" and was very pleased with himself for having committed them.

Case 7. Mr. G exemplifies a situation of narcissistic inadequacy defended by impulsive, grandiose action. He was 30 years old when he, like Mr. B, robbed a bank in San Francisco to give a beggar a quarter. The fact that he had to admit that he had no money when he was panhandled was such an internal defeat that he felt compelled to walk into the nearest bank and rob it. As he confronted the teller, he remembered thinking, "I could do anything; it was my moment of destiny. I really felt bad, seeing the teller so scared. I didn't want to hurt him or scare him too much, but I told him that I had a bomb in my pocket—nitroglycerin." He was given $3,000 and, frightened by what he had done, caught a plane to Hawaii. Once there, he immediately turned himself in and returned the remaining money.

As a child Mr. G had been deserted by his mother and raised in an orphanage called the New England Home for Little Wanderers. He had had a close relationship with his grandfather, a kindly Italian barber who died at about the same time he was abandoned. He felt that no matter how hard he tried, he could never be as good as his grandfather. When he left the orphanage he wandered, living out the orphanage's name. He was never without his teddy bear and transistor radio. He shoplifted candy and s... animals. He said these were "presents to my ...

A Marketplace Model of Consultation Psychiatry in the General Hospital

BY FREDERICK G. GUGGENHEIM, M.D.

The manner in which internists and surgeons view potential psychiatric consultations is analogous to the way in which consumers evaluate a service or product in the marketplace. Factors that determine a purchase or a consultation request include 1) perception of need, 2) prior attitude and experience, 3) projected image, 4) availability, and 5) cost/benefit ratio. The author presents a model of psychiatric consultation, with similarities between research and development, manufacturing and merchandising phases on the one hand, and negotiation, investigation, and implementation phases on the other.

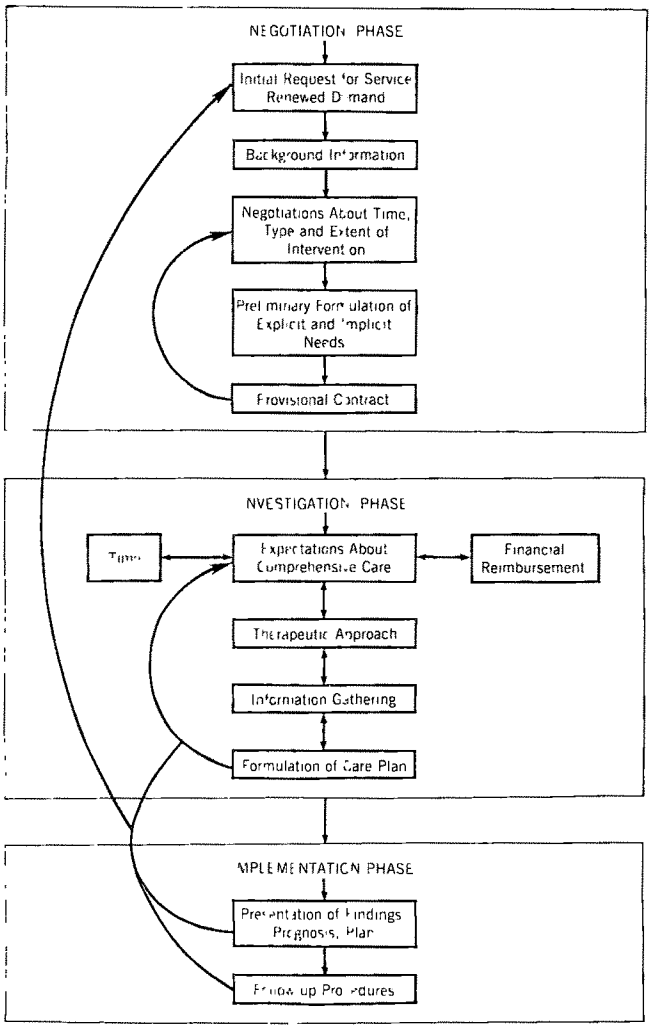
OUR UNDERSTANDING of the interactions of the psychiatric consultant in the general hospital has evolved considerably over the past two decades. At first, the consultation process was conceptualized as primarily a dyadic relationship (1, 2). Then it was seen as a pluralistic one (3–5). More recently, the consultation process has been represented by a general systems model (6, 7). The general systems approach, currently used in teaching residents about the complexities of consultation work, has been helpful in explaining the multifaceted interactions of the consultant with patients and their families and employers, members of the health care team, and the physician who has requested the consultation (termed the consultee in this paper).

General systems theory has permitted an understanding of the consultant's direct and indirect interactions with the patient and his milieu. Unfortunately, the theory as presented to date has not taken into account complexities of the general hospital as a sociological structure with powerful opinion-swinging constituencies that can accept or reject the consultant. It has also failed to focus on the consultant's roles as good will ambassador and salesman (in addition to his usual roles as physician, psychiatrist, and psychotherapist). Finally, general systems theory does not present forcefully the concept that psychiatric consultations can provide a substantial benefit at a definable cost.

Dr. Guggenheim is Assistant Professor of Psychiatry, Harvard Medical School, and Associate Psychiatrist, Massachusetts General Hospital, Fruit St., Boston, Mass. 02114, where he is also Director, Private Psychiatric Consultation Service.

Expanding on a general systems approach, I would like to present a marketplace model as an aid in explaining certain aspects of the consultant's interactions in the general hospital. Since the selling of a service is involved, the general hospital can be seen as the consultant's marketplace, the consultation as the consultant's service or product, and the consultee as the purchaser. Viewed in this way, certain rules and roles can be carefully examined.

For purposes of comparison, one can conceptualize the introduction of a new product to the marketplace or a service in the general hospital as having three separate but coordinate phases: 1) research and development, 2) manufacturing, and 3) merchandizing, with purchasing, consumption, and renewed demand. In merchandizing, advertising and good will are important factors. Image is a central issue; the appearance of substantial worth is as important a determinant of the business venture as the reality of its worth.



In consultation work, the three separate but coordinate phases are negotiation, investigation, and implementation. Figure 1 depicts the marketplace model as it applies to these three phases of the consultation process. In the negotiation phase, the initial request for service leads to a marketing survey and a provisional contractual agreement: Before agreeing to the consultation, the consultant needs to know how emergent the clinical situation is, what the problem is, and how the patient feels about being seen. Finding out that a patient is agitated, threatening others in the hall with her cane, limits the need to ask how she feels about being seen by a psychiatrist. If she needs to be seen instantly and the consultant has no available time for the next three hours, the consultee's expectations are a moot point. After negotiations about specifics of the intervention, a preliminary formulation of explicit and implicit needs leads to a provisional contract.

The investigation phase involves dynamic interaction among consultant, consultee, patient, family, nursing staff, and, occasionally, employer or sponsoring agency. The consultant's enthusiasm, perceptiveness, skill in interpersonal relationships, and technical skills, manifested by a positive therapeutic approach, greatly influence the "yield." Reactions to the consultant will influence staff availability in information gathering and care plan formulation.

Two other factors that influence the success of this phase are time and money. Although they are rarely discussed in the literature, they are of crucial impor-

FIGURE 1
Marketplace Analogy for Consultation Psychiatry

tance. The effectiveness of the best consultant will be diminished if his available time is severely limited. In practice, those consultants who squeeze consulting time out of a packed schedule rarely perform consultation that is up to their level of capability. Financial reimbursement also influences the quality and volume of work produced by the consultant. The consultant retained on a salary often engages in staff education, mediation of staff-staff conflicts, and patient-oriented preventive mental health measures. However, if the consultant is merely called in on specific cases and his anticipated payment is scanty and inconsistent, he may not deal with certain relevant, evident problems that directly or indirectly impinge on care. Factors like time and money determine whether the consultation process involves secondary and tertiary preventive measures or primary prevention.

Following the information-gathering phase, the consultant formulates with the staff a realistic care plan that is oriented toward the pathological [illegible] ing the patient, a diagnostic/descriptive [illegible] the patient's illness, i.e., his psychosoci[illegible] that disease, a dynamic/interpretive pr[illegible] consultant's understanding of the patie[illegible] and behavior allows for a comprehe[illegible] that includes concrete suggestions abo[illegible] behaviors for the staff and medication[illegible] for the patient (9).

The implementation phase of the co[illegible] ess is analogous to the merchandising [illegible] ness. Manufacturing is important, and [illegible] tant's gathering of information and form[illegible] namics. The crucial matter, however [illegible] tee's accepting and then implementing [illegible] recommendations. Far too often the [illegible] consultant underestimates the impo[illegible] plementation phase. Thus, he places litt[illegible] selling his suggestions to the consultee [illegible] try to overcome the mild suspicion wit[illegible] tees often regard consultations of all s[illegible]

In addition to selling his suggestion[illegible] needs to be certain that his goods are [illegible] packaged. New facts, and old ones re[illegible] be woven together into a product that is [illegible] the consultee. The consultant presents [illegible] pathology of the patient in light of the [illegible] experiences of the consultee. Some [illegible] open and curious consultees want a c[illegible] dynamic exposition of the family co[illegible] how it has played a role in the product[illegible] tional behavior. Other consultees, for [illegible] sonal and professional reasons, merely [illegible] list of suggestions about what to do wi[illegible] patient over the next few days.

The care plan must be adapted to the [illegible] providers in order to permit useful [illegible] rather than exasperated frustration. [illegible] follow-up support and prognosis should [illegible] vided. Proper attention to the implem[illegible] leads to mediation of disputes, easier co[illegible] better cooperation (10), and renewed [illegible] service.

Image is central to these phases. As [illegible] place, the projected capacity for a th[illegible] proach is as important to the process of [illegible] is the consultant's actual capacity for [illegible] gagement. Visibility, dependability, cred[illegible] cality, and accountability are factors tha[illegible] consultant's image. Also referred to as [illegible] demeanor" and "bedside manner," image [illegible] tant element in clinical practice and can [illegible] tential consultee's decision whether or [illegible] consultation. Reactions to the consultan[illegible] al demeanor influence staff availability [illegible] gathering and staff participation in the fe[illegible] implementation of a care plan. Staff [illegible] work enthusiastically to implement the s[illegible] a consultant who smoothes patient-staf[illegible] contrast, they often fail to follow the adv[illegible]

tants who interact with only the patient and chart or who use psychoanalytic jargon.

THE PURCHASE

The consumer's decision about buying the service or product is the crucial part of the complex chain of events in the marketplace. The buyer may have heard good things about the product and may have used it. He may have obtained funds for the purchase. Is the product available when the buyer wants it? To translate this to consultation work, Is the consultant both physically and emotionally receptive to the consultee's request? The consultant can choose the rules for his role, limiting or facilitating access, erecting dense or subtle barriers. These rules often arise from countertransference, the consultant's feelings regarding patients, staff, consultees, and institutions. Inexperienced consultants often are unaware of the ways they "turn off" staff.

A variety of factors influence consumer resistance and attraction toward the purchase. Neither the consultant nor the manufacturer has control over certain determining factors in a potential consumer or consultee, such as prior attitudes and experiences. Moreover, leaders' opinions can influence a potential purchase. If the chief of a medical service belittles the value of consultation, the proportion of staff seeking consultations for anything but "psychiatric disasters" may be rather small.

Cost of the consultation is another factor that influences the purchase decision. Generally, the cost to the consultee is small. He mentions to the patient that a psychiatrist will be stopping by to talk about problems, coping, pain, grief, nerves. However, if the referral is poorly timed or clumsily executed by the consultee, the cost may be an angry attack from a patient who feels punished or rejected. Making matters worse, some inexperienced consultants unfortunately do antagonize their patients with stressful interviews, seemingly irrelevant questions, and premature interpretations.

Some habitual nonconsultees never purchase psychiatric consultation because "it only stirs the patient up." Here the nonconsultees' fears of cost or of the unknown (e.g., dismissal from the case or displacement in important managerial decisions) (11) are important. Other habitual nonconsultees never even perceive a bona fide need. Surgical specialists, for example, often see their care as segmental, not comprehensive. They tend to seek psychiatric consultations infrequently (10); when they do, the patient is often a psychiatric disaster, with full-blown delirium tremens, homosexual panic, or severe suicidal ideation.

Although the consultant cannot control the effects of prior attitudes, experiences, and perceptions, he does have considerable input into his image. Public relations based on visibility, dependability, accountability, interest, and practicality can do much to swing potential users toward requesting a consultant's services at appropriate times.

OUTCOME EVALUATIONS

How can the vendor find out about the quality of his work? Industry typically spends 5% of its budget on research and development, including polls of consumer trends and satisfaction. The presence of objective measures and quantifiable outcomes aids both the precision and accuracy of the survey and permits perception of "blind spots."

In industry and intensive individual psychotherapy paid for by the patient, there is but one knowledgeable critic: the individual consumer. In consultation psychiatry, there are a number of critical consumers: the patient, the consultee, the family, the staff, and the institution.

Measurable outcome for the patient, in addition to satisfaction, might include decreases in anguish, overutilization of medical facilities for psychogenic problems, psychogenic invalidism, and noncompliance with medical regimen (12).

For the consultee, the immediate clinical impact of the consultation outcome might be an increased level of awareness and understanding of relevant psychosocial factors. This in itself is difficult to quantitate. However, a derivative behavior might also ensue—increased facilitation in the identification of problems amenable to specific intervention. This transformation might then lead to such measurable change as an increase in the referral rate, along with earlier detection of problems and greater implementation of the consultant's suggestions.

For the staff, effective consultation work might lead to a decrease in staff turnover and perhaps to improved morale and higher levels of comprehensive care.

Another important outcome question is how much profit is being generated. In an era of scarce funds and a need for continual examination of cost-benefit ratios, this is a crucial question. Improvement of comprehensive care is the goal of consultation work. In this respect, it differs from industry, where the goal is monetary profit. In the case of a university consultation service, "profits" can be examined in terms of 1) improved comprehensive care, which is hard to quantitate; 2) teaching, which is easier to assess in terms of number and types of conferences plus student critiques and performance; and 3) research, which is also easier to measure in terms of quantity and quality of original and scholarly contributions.

THE BOTTOM LINE

Examination of the marketing process entails a step-by-step review of each phase, with objective descriptions of corporate strengths and weaknesses. The sim-

plest way to do a "quick and easy" quantitative, quasi-qualitative overview of any business is to inspect the bottom line—how much profit is being generated, how much work is being done?

The referral rates of consultation and liaison services from various medical centers have been published. Lipowski (10) reported a range of 4%–13% of all admissions, with an average of 9%, but some figures from academic settings are as low as 2.2% (13). British studies cite referral rates of 0.7% and 1.34% (14, 15). Although Lipowski (10) stated that American consultation services have higher rates of referral than European services, he is unclear on the reason for this. Since some of these figures group wards with liaison activity, they need to be looked at with a critical eye. The referral rate on a liaison service may be 35% (16), while that for a private psychiatric consultation service in the same hospital without a liaison service runs about 4% (17). Hospital-wide psychiatric consultation rates are a complex matter, reflecting, among other things, availability and adaptability of manpower, image, and departmental-institutional goals and priorities.

Although it plays a pivotal role in the commercial marketplace, formal quality control inspection is often lacking in consultation work. The consultant's lack of meaningful feedback deprives him of an important stimulus to learning. Therefore, a quantitative measure (the number of consultations requested) is usually the only quality control measure built into consultation work, although qualitative criteria could possibly be applied. For example, is the consultant called in appropriately early? Are his opinions valued and suggestions carried out? Does his intervention appear to improve comprehensive care?

CONCLUSIONS

A marketplace model points out the interactive and interdependent nature of consultation work. Insufficient attention has been paid to the implementation phase of consultation work. Inexperienced consultants often attend to information-gathering r[illegible] total consultation process.

Despite its demonstrated benefit to c[illegible] care and its relatively minuscule cost [illegible] other health and mental health care acti[illegible] tation psychiatry continues to be under[illegible] dizing the activities of a viable and use[illegible] patient care.

A Look at Psychiatric Decision Making

BY BRUCE ROBERTS, M.D.

The author reviews the efforts of medicine and psychiatry to understand their decision-making processes and notes the lack of psychiatric literature in this area. The decision table, a sophisticated form of algorithm, is introduced as a structure to help explain the decision-making process. This tool is applied to the evaluation and biological treatment of depression. Decision tables can be used as an educational tool, a method to facilitate the delivery of mental health care, a method to monitor the quality of treatment, and as a research tool.

IN POSTGRADUATE training and particularly medical school, psychiatry and the other medical specialties have typically emphasized the acquisition of bodies of knowledge as opposed to an understanding of the decision-making process. Specific factual data obtained from lectures, books, and journals are important, but what seems to be at least as important, or more important, is the ability of the psychiatrist (physician) to use these diverse data for making appropriate decisions. A systematic explanation of logic for good decision making is presently not being taught. I propose that decision tables may help us to better understand how we make decisions.

In the past decade there has been an increasing interest in objectifying clinical judgment. Gauron and Dickinson (1, 2) investigated how 12 psychiatrists arrived at clinical conclusions in 40 hospital cases. They found 5 basically different diagnostic approaches.

1. Some psychiatrists committed themselves to a diagnosis on an intuitive basis early in the process and then challenged the rest of the information to disprove this diagnosis.
2. Some psychiatrists could not narrow the number of possible diagnoses and made an impulsive, arbitrary decision to choose one diagnosis.
3. Some psychiatrists considered every possible diagnosis with equal weight and ruled out each one systematically.
4. Some psychiatrists rigidly followed a formal structure, i.e., a textbook, and requested a tremendous amount of data before diagnoses were ruled out.
5. Some psychiatrists went where the information led them and had no preconceived notions of the diagnosis.

Some work in statistical decision theory (3–5) and the use of algorithms (4, 6) has further expanded the application of decision analysis to medicine and psychiatry. With this work has come a tremendous interest in the organization (7) and computerization of psychiatric and medical data (4, 7–18). In the past five years, particularly in the past two years, there has been a great deal written in medical journals on the application of decision analysis to medical problems (19–31) and relatively little written about this in the psychiatric literature.

A new technique, decision tables, has recently beeen introduced in the medical literature by Holland (32). The application of this technique to psychiatry is the substance of this paper.

DECISION TABLES

Decision tables were developed in the late 1950s by the General Electric and Sutherland companies to replace algorithms that could not handle the complexities of their manufacturing processes. Since their development, the literature has been full of stories of how decision tables succeeded where older techniques, i.e., algorithms, failed (32, 33). Decision tables compactly represent a great deal of data, logically linking the variables (conditions) and outputs (actions), and they are commonly used in business and government.

To illustrate the application of decision tables, I shall transfer the logic contained in the following ancient Persian poem (32) into a decision table:

He who knows not and knows not that he knows not is a fool—shun him.
He who knows not and knows that he knows not can be taught—teach him.
He who knows and knows not that he knows is asleep—wake him.
He who knows and knows that he knows is a prophet—follow him.

This poem can be written in the decision table

At the time this work was done, Dr. Roberts was a resident, Department of Psychiatry, University of Vermont College of Medicine, Burlington, Vt. He is now Assistant Professor of Psychiatry, Abraham Lincoln School of Medicine, West Side Veterans Administration Hospital, P.O. Box 8195, Chicago, Ill. 60680.

The author wishes to thank Stewart Graves, M.D., for his help and encouragement and Lawrence L. Weed, M.D., for his moral support of the ideas expressed in this paper. Drs. Graves and Weed are with the Problem-Oriented Medical Information System Laboratory at the University of Vermont College of Medicine.

FIGURE 1
Decision Table for Ancient Persian Poem*

CONDITION	1	He knows	Y		N	
	2	He knows that he knows not	—		Y	N
	3	He knows that he knows	Y	N	—	—
ACTION	1	Shun him				X
	2	Teach him			X	
	3	Wake him		X		
	4	Follow him	X			

*All items above the double lines are the conditions. Y indicates that the condition is present, and N indicates that the condition is not present. A condition that is not needed or is irrelevant to the particular pathway is represented by a horizontal line. All of the items below the double line are the actions (outputs). X indicates that the action to the left of the X is to be initiated. This illustration is based on material from Holland (32).

shown in figure 1. In figure 1 all of the items above the double line are the conditions. If the condition is present it is represented by a "Y" to the right of the condition. If the condition is not present "N" is the correct choice. A condition that is not needed or is irrelevant to the particular pathway is represented by a "—" to the right of the condition. All of the items below the horizontal double line are the actions (outputs). In the area below the double line "X" indicates that the action to the left of the "X" is to be initiated.

As an illustration, let us assume that we want to know the outcome of "He who knows and knows not that he knows." Choose "Y" for condition 1, "He knows." Condition 2 is immaterial under "Y." Proceed to condition 3, "He knows that he knows." For condition 3 we want the negative of "He knows that he knows," and we therefore choose "N." Drop a vertical line under "N" in condition 3, and the "X" under the horizontal double line is the output, "Wake him," action 3.

DECISION TABLE FOR THE EVALUATION OF THE CHIEF COMPLAINT OF "FEELING BAD"

To illustrate the use of decision tables to facilitate objectifying the diagnostic process, let us look at the problem of a patient with the chief complaint of "feeling bad." The novice may feel overwhelmed by the various options he/she may pursue for this chief complaint. The novice must learn what decision to make and assign priorities to these decisions. The experienced psychiatrist will more efficiently recognize (it may not be conscious) the priority of decisions he or she must make without prematurely closing off hypotheses. The decision table shown in figure 2 attempts to objectify this process. I do not propose that it represents the only or best way to evaluate the chief complaint "feeling bad." However, it will facilitate understanding the *process* (not the conte[illegible] think.

The decision table in figure 2 propose[illegible] decision which should be made is to de[illegible] er the chief complaint of "feeling bad" [illegible] tation of depressed mood. If the patien[illegible] is anxious when he says he is "feeling [illegible] 1 is "N." The appropriate action for [illegible] tient is determined by dropping a line [illegible] condition 1. Conditions 2–7 are imma[illegible] vertical line would intercept "X" at ac[illegible] not the manifestation 'depressed mood[illegible] festation, i.e., anxiety, fear, etc., nee[illegible] uated in another decision table." Thus [illegible] sumption that this is a depressed mood[illegible] one is directed to another decision table [illegible] fined in this text, i.e., in actions 1–8, on[illegible] be directed to reenter this decision table[illegible]

Assuming that we are dealing with the [illegible] depressed mood, we see that condit[illegible] lowing the vertical line in figure 2 we pro[illegible] tion 2 and need to make a decision to de[illegible] er the patient is an immedite danger to h[illegible] ers. It seems judicious that this deci[illegible] before considering the possibility of a bi[illegible] ment. Let us also assume that the pati[illegible] ideas but is not an immediate danger to i[illegible] ers—thus condition 2 is "N"; that there [illegible] loss of a major love object—thus condit[illegible] making condition 4 immaterial; that th[illegible] dence of psychotic behavior or diagno[illegible] phrenia—thus condition 5 is "N"; that a[illegible] organic etiologies have been ruled ou[illegible] nist—thus condition 6 is "Y"; and that t[illegible] never been successfully treated for this p[illegible] past—thus condition 7 is "N." This pro[illegible] in figure 2 by the vertical line. This line [illegible] "X" at actions 7 and 8.

The reader may ask, "How do you esta[illegible] patient is an immediate danger to himse[illegible] or "How do you determine if the 'depre[illegible] part of a normal grief reaction?" Deci[illegible] facilitate asking these questions. Organi[illegible] tion around relevant decisions gives a n[illegible] to factual data. Each condition (1–8) an[illegible] may require a decision table of its ow[illegible] beyond the scope of this paper.[1]

Despite what may appear to be a rigid [illegible] decision table should be used as a tool fo[illegible] trist and should not interfere with the ps[illegible] tient relationship. The use of a mechan[illegible] psychiatrist's thinking does not mean th[illegible] ous verbal information from the patient i[illegible]

Because the psychiatrist has used the [illegible] in figure 2, he or she is assured that he has [illegible]

[1]A decision table is available from the author on req[illegible] in figure 2. This decision table defines a model to de[illegible] er a biological intervention is indicated, and if it is [illegible] the intervention should be.

FIGURE 2
Decision Table for the Evaluation of the Chief Complaint "Feeling Bad"*

CONDITION	1	Verify that the chief complaint "feeling bad" is really the manifestation "depressed mood."	Y									N
	2	Is patient an immediate danger to himself or others?	N								Y	—
	3	Is there a recent loss of a *major* love object?	Y				N				—	—
	4	Is this part of a normal grief reaction?	N			Y	—				—	—
	5	Is there evidence of psychotic behavior or diagnosis of schizophrenia?	N		Y	—	N			Y	—	—
	6	Have all appropriate organic etiologies been ruled out?	Y		N	—	—	Y	N	—	—	—
	7	Has the patient been successfully treated for this problem in the past?	Y	N	—	—	—	Y	N	—	—	—	—
ACTION	1	This is not the manifestation "depressed mood." This manifestation, i.e., anxiety, fear, etc., needs to be evaluated in another decision table.										X
	2	Make a management decision to prevent an immediate suicide or homicide attempt.									X	
	3	This patient may need support, but does not need any major psychiatric intervention.					X					
	4	The patient's depressed mood may be a manifestation of a psychotic illness. This requires more information about the nature of the psychotic illness before a treatment decision can be made.				X				X		
	5	The patient's depressed mood may, in whole or part, be a manifestation of an organic illness. Rule out all appropriate organic etiologies for this age group.			X				X			
	6	Integrate this information into the evaluation. You may reenter this table at action 7 if you are not sure of treatment plan.	X					X				
	7	Now determine if patient will benefit from a biological treatment for "depressed mood." Go to biological treatment of depression decision table.		X					X			
	8	Evaluate for appropriate psychotherapy.		X					X			

*See figure 1 for an explanation of the symbols used here.

responsibilities. He knows that he has a patient with a depressed mood, whom he has evaluated for immediate suicide and homicide potential, for a normal grief reaction, psychotic behavior, and possible contributing organic factors. If the psychiatrist has used the decision table and has kept good records, he can justify his logic both to the patient and the peer review committee.

CONCLUSIONS

Decision tables may be used as an educational tool, a method to facilitate the delivery of mental health care, a method to monitor the quality of treatment, and as a research tool.

Decision tables focus on the process of integrating diverse information for making appropriate decisions. This is in contrast to the present method of trying to teach medical students all of the data and leaving it to them to integrate these data to solve problems. In our present system, it is hoped that when a medical student sees a patient and is confronted with the patient's problems, he or she will somehow remember the relevant data and know how to apply it to evaluate, define, and solve the presenting problem. We know that this does not happen; what is closer to real life is that medical students learn clinical judgment by their own devices. Some learn it better than others. Time is constant (4 years), and quality becomes the variable. Since the core curriculum focuses on the regurgitation of facts, this attitude still pervades in the clinics. The emphasis on regurgitation of facts is out of proportion to the emphasis on decision making.

When used appropriately and not overzealously, decision tables can facilitate mental health care. They are efficient in defining a relevant data base. The process of obtaining the data is a dynamic one, the variable being the answer to the previous question. Decision tables facilitate logical thinking and help us define what we know and do not know. They minimize the pretentious illusion of knowledge when we do not have the data.

Keeping a good record of the decision-making process enables the psychiatrist to document his or her logic. This creates a mechanism for the psychiatrist to be accountable to the patient, the peer review committee, and himself.

Decision tables can be useful tools in psychiatry as a mechanism to expose and explore how we think.

Videotape Recording of Dynamic Psychotherapy: Supervisory Tool or Hindrance?

BY CLAUDE T. H. FRIEDMANN, M.D., JOE YAMAMOTO, M.D., GEORGE H. WOLKON, PH.D., AND LYNDA DAVIS, M.A.

The authors questioned residents and supervisors at a large clinic about their attitudes and experiences regarding clinical supervision. Half of the residents then videotaped one of their psychotherapy sessions and presented the tape in their next supervisory session. The procedure had little effect on patients, was anxiety-provoking for the residents, and had some diagnostic benefit for the supervisors. After the taping, the residents' views about taping were less positive than before the taping, but the supervisors' views did not change significantly.

THE TEACHING of dynamic psychotherapy in the United States relies heavily on secondhand reporting of clinical material by a resident to a supervisor. This methodology, devised by Eitington (1) for the Berlin Psychoanalytic Institute, is considered a cornerstone of psychiatric education. It departs in several ways from the medical model of direct patient examination by the attending physician: 1) it assumes that the reporter will give a reliable account and that the supervisor will be able to recognize gaps and errors, 2) the therapeutic process as reported over time is assumed to be more important than a detailed presentation of each hour (2), and 3) the resident's relationship with the supervisor is considered very important and the patient is not per se the focus of the discussion. Fleming and Benedek (3) consider supervision to be parallel to psychoanalysis.

The nature and goals of supervision are in debate. Tarachow (4) disagrees with Fleming, stating that supervision should be patient centered. Sloane (5) would not deal with countertransference issues, but Goin and Kline (6) encourage it. Some would concentrate on supervision as a growth experience and stress residents' own intrapsychic dynamics, whereas others prefer to focus on diagnosis, therapeutic techniques, and the patient.

Gruenberg and associates (7) point out that traditional supervision, regardless of goals, is subject to conscious and unconscious editing and misperceptions and that the therapist is often unaware of his or her nonverbal communications. Gruenberg proposes videotaping sessions to improve residency education. Grotjahn (8) also voices misgivings about traditional supervision, as do Schuster and associates (9). When Schuster saw puzzling patients "live," he often received a very different impression than previous reporting had given him. Stein and associates (10) related bias in the initial interviews of patients after comparing secondhand supervision with live observation. Buehler (11) also found discrepancies between written reports and direct observation.

In the 1950s the Conference on Psychiatric Education (12) held that audiovisual media have little place in psychiatric education, and Eckstein and Wallerstein (2) agreed regarding dynamic psychotherapy. When Kubie (13) suggested tape recording analytic sessions he met great resistance, including a feeling that the study of supervision was inappropriate. Questions have been raised about the effects of videotapes, one-way mirrors, audiotapes, and direct observation of the therapist and patient, as well as fear of artifactual interference with the therapeutic process. Others see these tools as fostering passivity (14) and diminishing the necessity for case formulations by trainees (15).

In this paper we will address several of these unanswered questions. We queried psychiatric residents and their supervisors about the nature and goals of supervision and their feelings about videotaping for supervision and attempted to gauge the effect of the videotaping procedure on all the participants. We will submit some preliminary data regarding the effect of videotaping a session of continuing, traditionally supervised psychotherapy for supervision. To our knowledge, this is the first attempt to systematically assess the value of videotapes in continuing supervision versus secondhand reporting. Although we will

not provide the definitive answer of whether or not a picture is worth a thousand words, we hope to provide a sound basis for future scientific study.

METHOD

All of the clinical supervisors and second-year psychiatric residents in the Adult Psychiatry Outpatient Clinic of the University of Southern California-Los Angeles County Hospital were asked to complete a questionnaire about their clinical supervision. Most of the supervisors were private practitioners in the community, but a few were full-time faculty. The majority had a dynamic-analytic orientation. Second-year residents were working full-time in the outpatient clinic for the entire year, spending over 100 hours a month seeing patients. Our questionnaire contained a rating scale to assess experience with various modes of supervision, the supervisors' and residents' perception of the goals of supervision, and their opinions regarding the potential impact of videotaping one session of psychotherapy currently under traditional supervision.

Next, all of the residents were asked to videotape such a session and to use the tape during the next supervisory session. Permission from the patient and supervisor were required. Half of the residents, 11, volunteered. The taping residents and their supervisors were required to complete a modified Walter Reed Mental Status Evaluation (16) for their patient before taping and after viewing the tape. After viewing, they completed a questionnaire about how they felt the taping affected the patients, themselves, and the supervision.

The videotaping was performed by volunteers who used portable equipment set up in the therapist's office. The viewing was done in another, specially equipped room. The supervisors and residents answered the questionnaires in private and without consulting each other. The patients completed a short questionnaire after the taping that indicated their feelings about the session.

RESULTS

Previous Experience with Videotapes

We obtained responses from 21 of the 22 residents (95%) and 32 of the 37 supervisors (86%). On the average, each resident had worked with 50 outpatients and each supervisor with 50 residents. Only 16% of the residents and 40% of the supervisors had previously used videotapes in the supervision of psychotherapy. None used them regularly, and each used traditional supervision at least 85% of the time. There was no significant difference in previous experience between the 11 residents and 9 supervisors who subsequently videotaped a therapy session for this study and the 10 residents and 23 supervisors who did not. There were 2 supervisors who supervised 2 participating residents each, hence the discrepancy between the number of supervisors and 11 residents.

Opinions About the Goals of Supervision

The items considered by our respondents as "very much" goals of supervising psychodynamic psychotherapy were teaching psychodynamics, improving therapeutic techniques, improving patient care, and helping residents grow. The remaining 4 items were rated as "somewhat" important goals: giving emotional support, teaching psychiatric theory, teaching diagnostic techniques, and getting residents in touch with their own feelings. No categories were rated as "little" or "no" importance. There was a high degree of agreement across all 4 groups—residents who participated in a videotaped session and those who did not, and supervisors who participated and those who did not.

Attitudes Toward Videotaping

Before videotaping. The supervisors who were involved in videotaping and the residents with whom they showed significantly stronger agreement than the supervisors who were not and the residents with whom they agreed with the statement that videotaping would interfere with the patient's production of material ($t=2.$ $p<.01$, and $t=1.88$, $p<.05$, respectively). Residents in the taped session, although all 4 groups of residents agreed with the statement that taping would interfere with the resident's ability to conduct psychotherapy, nontaping supervisors had significantly higher expectations than the taping supervisors that videotaping would be more helpful than secondhand reporting in giving the resident self-understanding ($t=2.$ and in assessing the resident's clinical abilities ($t=1.$ $p<.05$). The taping residents saw the videotape as being significantly more helpful than the taping supervisors in understanding techniques ($t=2.50$, $p<.0$) and in making them a better therapist ($t=2.12$, $p<.05$). Thus the taping residents had more positive expectations about the benefit of videotaping than did the supervisors they were working with.

After videotaping. When we analyzed the responses to the videotape data for the 11 residents and their supervisors who participated in the taping, we noted significant shifts: despite pretape opinions that videotaping would interfere minimally with therapy, the supervisors involved in the taping showed a significant trend ($t=1.89$, $p<.05$) toward viewing the taping as interfering with the resident's ability to treat patients. Prior to taping, the residents felt their supervisors would be more technique oriented during the supervision using the tapes; subsequently they found the supervisors less technique oriented ($t=2.42$, $p<.0$ and found the videotapes less helpful in understanding techniques than they had anticipated ($t=2.$ $p<.05$).

Overall, the supervisors' pre- and post-taping views of videotaping for supervision did not differ significantly. However, residents' views became more po-

tive: of 199 possible responses, only 28 changed in a favorable direction, whereas 69 moved in a negative direction and 102 remained unchanged.

Patient Responses

Five patients reported that they were moderately anxious during the study, 1 reported being very anxious, and 5 said they were slightly or not at all anxious. None "greatly disliked" it, and 3 "greatly enjoyed it." All but 2 said the taping made the session "different" from all previous sessions, but the consensus was that the session was no worse nor better than any other and that they would not have said anything different had the session not been taped. Two-thirds of the patients said they would like to be taped again; the rest said they would not. These opinions contrast with those of the residents and supervisors, who felt the videotape had "somewhat" interfered with the patients' production of material, and agree with their estimations that the patients were "somewhat" more anxious during the session.

Rating of Patient Pathology

The taping residents and supervisors rated the patients in 102 specified areas of the modified Walter Reed Mental Status Evaluation (16). They estimated the degree of pathology and their confidence in these ratings before and after taping. Responses for each rating category were summed across all items and an overall confidence rating was obtained for both questionnaires. The supervisors were significantly more confident of their estimates of pathology after viewing the tape ($\chi^2=88.71$, df=3, $p<.01$). Residents' confidence ratings did not change significantly.

Comparisons of the pre- and posttape questionnaires revealed no statistically significant changes by either the residents or supervisors involved in the taping in terms of the nature or degree of pathology, diagnosis, or prognosis. However, for 3 patients the working diagnosis was altered by the supervisor as a result of the videotaped session. One was changed from depressive neurosis to passive-aggressive personality, 1 from anxiety neurosis to depressive neurosis, and in one case the diagnosis of passive-dependent personality was added to the previously perceived diagnosis.

DISCUSSION

Effects of Videotaping on Patients and Residents

Our data indicate that the videotaping of psychotherapy is not disruptive to the patient. Aside from experiencing a moderate increase in anxiety, the patients tolerated the procedure well and reported that it had no significant effect on their production of material or the therapy itself. Those who fear that videotaping is artifactual, intrusive, or counterproductive should be reassured.

Both taping residents and taping supervisors found that the videotaping was interfering and anxiety producing for the resident. Several explanations for this are possible: 1) that the residents were actually no worse than usual in these sessions but had unconsciously or consciously made themselves look good in prior supervision, as discussed by Stein and associates (10), 2) that the residents were afraid that the supervisor might use the videotape to evaluate the resident, or 3) that the supervisors were inexperienced in deriving maximum educational benefit from videotaping. Our data support Gruenberg (7), who feels it is the therapist, not the patient, who is inhibited by taping. Foreknowledge of the normalcy of such anxiety might diminish resistance to such procedures.

The Videotape and Assessment of Patient Pathology

Seeing the patient on tape had several effects on the supervisors. Prior to the taping they were rather unsure of their assessments of patient pathology, a fact that supports Grotjahn's feeling (8) that traditional supervision creates a great deal of uncertainty for the supervisor. Subsequent to viewing they became much more confident of their answers. Moreover, three supervisors made changes in the diagnoses given the patients. At least in some cases videotape can be of major diagnostic value.

The failure to produce more significant changes in patient assessment, such as those described by Stein and associates (10), Schuster and associates (9), and Buehler (11), may indicate that the initial interview situation is more subject to distortion than continuing cases wherein patients are discussed week after week. More pessimistically, it may be much more difficult to change one's opinion about a patient after several weeks of doing what one assumes is worthwhile and accurate supervision.

Videotapes and the Goals of Supervision

The unanimity of the respondents regarding the purpose of supervision deserves close scrutiny. The dichotomy found in the literature between the student-centered and patient-centered schools of supervision is not evident among our sample. Clearly, all aspects of psychiatry, including teaching clinical skills, improving patient care, and helping residents with their own problems, are acceptable goals. This sample, representing a significant percentage of our clinical staff, would accept a middle position between Tarachow (4) (patient-centered) and Fleming and Benedek (3) (supervision=therapy), disagree with Sloane (5) (teach only), and agree with Goin and Kline (6) that the resident's own feelings are important to discuss.

Although our respondents showed unanimity in regard to the goals of supervision, before taping there was some disagreement between the taping residents and supervisors about the uses of the videotape; the taping residents were more optimistic. After the supervisory session, however, the residents in general were disappointed. This disappointment could reflect the aforementioned differing expectations. Perhaps resident-supervisor teams could have profited by joint in-

struction on the educational uses of videotapes. The newness of the single videotape, without significant prior experience, possibly created problems, and multiple continuous taped sessions may be needed before its usefulness can be adequately ascertained.

CONCLUSIONS

Our data indicate that the videotaping of continuing psychotherapy for supervision is not harmful to patients, increases supervisors' certainty about diagnosis, and makes residents anxious. Better education regarding use of the technique, plus more extensive and controlled comparisons of taped and secondhand supervision will be needed before any clear-cut decisions about the educational value and cost effectiveness of such procedures can be made. The videotaping procedure is, at least, not a hindrance to supervision and is, to some extent, a valuable tool.

Psychiatry Residents in a Milieu Participatory Democracy: A Resident's View

BY DENNIS GERSTEN, M.D.

Psychiatry residents respond with a variety of coping mechanisms to the lack of traditional structure in a milieu participatory democracy. To incorporate themselves into the system they must accept such democratic ideals as equality among staff and patients, group decision making, and free self-expression and give up some of their traditional ideas about staff and patient roles, treatment modalities, and the therapeutic environment. The author was a first-year resident in psychiatry on a university hospital inpatient therapeutic community; he discusses the conflicts between residents, who often adopt a "we-they" attitude, and the permanent staff, whose protectiveness of the ward community reflects their personal commitment to its ideals.

IN THE LAST FEW DECADES there has been an increase in the use of the therapeutic community for treating psychiatric inpatients. Although a lot of attention has been paid to patients' reactions to this type of system, little work has focused on the experience of residents in training in this setting. In this paper I will discuss psychiatric residents' experiences in such a system, the difficulties they encounter, and the coping styles they can adopt.

THE PHILOSOPHY OF THERAPEUTIC DEMOCRACY

In a therapeutic democracy there is no autocratic leader (whether a benign dictator or otherwise) to hand down decisions, but rather the community as a whole votes on almost all major issues and thus decides ward policy. Ward decisions are reached by vote and are presumably based on logic, common sense, and experience—not on formal credentials. The democratic policy extends to decisions on hiring and firing, role definition, promotion, discipline, and general ward policies. The implicit assumption in this therapeutic philosophy is that group decision is usually more valid than individual decision.

The concept of democracy extends to the treatment of patients. Decisions regarding patients' passes, class changes, discipline, responsibilities, and the management of difficult patients are voted on by staff and patients in community meetings. Each has an equal vote. Staff veto power exists but is rarely used. Staff-patient equality is fostered by the use of first names for everyone. Casual dress and the absence of identifying name tags or patient wrist bracelets emphasize the concept of equality.

The philosophy of democratic treatment includes the belief that this process will facilitate open and honest interaction between all community members and that the resolution of staff and staff-patient conflicts leads ultimately to good patient care. At the core of such a philosophy is the belief that it is possible to create an environment that is essentially humane and egalitarian and that patients improve by living in such an environment and integrating its ideals. The community process itself is thought to be the healing force (1)[1]. In practice, patients become members of the social system and are encouraged by their peers to act responsibly. They are rewarded for behavioral change by peers and staff.

A number of policies follow from these assumptions. Nonmedical staff ("primary contacts") are primarily responsible for coordinating patient care and use the resident as a supervisor. This modus operandi is prevalent in both traditional psychiatric hospitals and therapeutic communities in newer institutions. It accommodates changing treatment philosophies and aids nursing personnel who are in close contact with patients and who must make rapid decisions regarding patient care, often without concern for the power base (2).

THE RESIDENT'S EXPERIENCE

Entering the Milieu Environment

A psychiatric resident entering this system either directly from training on a medical ward or from a tradi-

tional psychiatric ward is often more than surprised at the disparity between his self-perceived role and community expectations. He may be called doctor; he may not. His opinions are not accepted automatically because he has a medical degree: on the contrary his ideas about patient management, treatment, or ward staffing problems may be actively contested. Finally, he will discover that the patients he has expected to treat are usually not his to treat alone—each step is a group decision. The therapeutic democracy conveys to the resident a sense of constant chaos and continual crises on the ward and a profound sense of a lack of structure, or at least structure with which he is familiar. As a result of his experiences in training, the resident must at first assume that the ward is in crisis and that it will soon pass. He searches for causality in the crisis. Is it one or two difficult patients, is it the residue from a suicide last week, is it because a manic patient is tearing the place apart? Is it because the staff disagrees on the treatment plan and argues over the smorgasbord of drugs, insight, psychodrama, and Gestalt therapy? Or is it because of me? Finding no satisfying explanation, a resident may feel at times as if he is being swept along in a crowd, not knowing its direction, purpose, or destination.

As time passes, the resident may realize that this apparent disorder is the status quo. He draws on the coping mechanism that has always worked to counter chaos—the insistence that structure and order be imposed. His obsessive style has conquered medicine, and surely it will not let him down now. Usually he makes a few random attacks on certain symbols of the system—"People here should wear name tags," "I should be called doctor," "You should be called nurse," "You should be called patient." "The nursing station should be off-limits to patients (or at least the nursing station should have a sign on it saying 'Nursing Station')." Only much later might he learn that these issues are symbolic of a much deeper philosophical stance.

In the early stages of my residency in a university hospital milieu-oriented psychiatric ward, I felt acutely stressed. I felt that there had been a shift in the traditional power structure. It was true that I was the doctor, who did histories, physicals, workups and ordered medications; and it was true that the patients tended to regard me with traditional expectations of giving medications, providing some definitive knowledge, writing orders, and arranging for discharges. However, there was a difference; my opinions were challenged, and I felt I did not have the respect I had earlier in my training. Such a sense of decreased self-esteem was facilitated by covert attitudes and overt comments by patients and staff. In either case, as a fledgling psychiatrist I interpreted a lack of respect for my budding professional identity as an attack.

The Resident's Response

Sooner or later a resident must meet the new challenges of the milieu unit with new solutions and find ways of dealing with the polarities that ofte[illegible]. The less flexible resident often becomes in[illegible] authoritarian, makes unilateral decisions, [illegible] technical language, and insists on traditional [illegible] nurse-patient roles. He regains a sense of co[illegible] at the same time increases polarities, incre[illegible] sive-aggressive staff interactions, and force[illegible] isolation. Because the idea of equality is a c[illegible] of democratic philosophy, the authoritar[illegible] tends to catalyze struggles around that iss[illegible] scapegoat, and in so doing increase the co[illegible] rest of the staff at his expense.

Obviously the resident's range of respo[illegible] ed only by the number of his defensive s[illegible] dent may be primarily passive-aggressive [illegible] gress to a dependent position and turn o[illegible] responsibility to nursing personnel, he [illegible] highly obsessive and lose himself in the [illegible] per work, or he may conform in his beh[illegible] significantly changing any of his values.

The riskiest stance for the resident is [illegible] behavior and attitudes—risky because [illegible] must be willing to surrender and sett[illegible] tudes and be "adrift at sea" for some [illegible] integrates all or part of a different set [illegible]

Whichever defensive stance a reside[illegible] a milieu-oriented ward he must conte[illegible] symbolic ideals. Spontaneity is hig[illegible] many of the staff encourage patients [illegible] tion freely. Implicit in this attitude is [illegible] self-expression leads to free will and [illegible] termine one's own fate. The extreme [illegible] attitude is the avoidance of seclusio[illegible] avoidance of medication because [illegible] emotions," and encouragement of [illegible] ences in everyone. Ultimately th[illegible] struggle between those who consid[illegible] manists and those who uphold th[illegible] Once while this struggle was raging [illegible] eral staff members suggested that [illegible] into seclusion in order to understa[illegible] dents would at times insist on using [illegible] seclusion in treating patients.

During this kind of struggle, [illegible] forceful ones, were seen as inhum[illegible] interested only in superficial chang[illegible] residents in turn saw the advoca[illegible] without medication" as poorly t[illegible] trating, and undermining. In ac[illegible] that the staff members who acc[illegible] and insisted on treating psychos[illegible] were themselves being cruel t[illegible] valuable therapeutic modalitie[illegible] tients' suffering. As physicians [illegible] ty to use and understand medica[illegible] becoming comfortable with [illegible] helped define their identities [illegible] disagreements over medicatio[illegible] dents profoundly. However, [illegible] this kind residents could begin [illegible]

psychotherapeutic techniques and were in fact able to offer good treatment using less medication, think out their use of medications more carefully, and use them more appropriately.

Many of the issues debated on the unit seem unrelated, but most derive from the basic ward philosophy and the inherent built-in power struggles. Much of the distortion of this ideal of democracy results from the natural failure of its total actualization. On the one hand, nursing personnel want the benefits of the increased status and responsibility of being primary contacts but on the other hand are often dependent and demanding of the resident; when work does not get done, the resident inevitably picks up the slack. At the same time that equality is fostered, there are clearly several areas where staff are not equal. Residents tend to be far better at diagnosis and the use of medication; certain nursing personnel are excellent psychotherapists. However, the tendency to blur individual differences in the name of democracy results in the smoke screen of a melting pot rather than the true plurality that does in fact exist.

WARD LEADERSHIP

Another major difficulty a resident faces is the lack of clear leadership by the ward chief. The ward chief with whom I worked was, like those described elsewhere (2), a charismatic figure whose primary mode of leadership was often his charisma alone rather than the exercise of the power traditionally inherent in the position. He generally chose to "lead from behind" and allow others to emerge, fostering a more egalitarian system. Like other charismatic leaders (3, 4) he functioned more as a catalyst for the process of community than as an authority per se. However, inherent in his position was latent authority, which he used in times of crisis.

With this type of leadership, many staff members became more creative and autonomous and felt a sense of achievement that they had not felt in other psychiatric hospitals. Residents, on the other hand, often did not highly value personal growth by the nursing personnel and indeed were threatened at times by their increased independence.

Residents often did not share the ward chief's understanding of his role and saw his "leading from behind" as an absence of clear leadership. The possibility that he too was swept along in and by the democracy was far too threatening for residents to consider.

In attempting to understand ward dynamics, residents often perceive a we-they position. Indeed, it was only after I began carefully exploring ward philosophy on an individual basis that I realized the fallacy of this attitude. There was, as in any culture, a large middle ground not radically doctrinaire but allowing some freedom in various directions at different times. However, when the ward became polarized around a given issue, residents often felt "either you're with us or you're against us" and the rest of the unit responded similarly.

Where they are actually practiced, the ideals of democracy seem to clearly enhance equality in dealing with one another. The major problem is that people often act as if they want a firm leader whose decisions they can both respect and rebel against. In the absence of such a leader the staff either become disorganized or find a scapegoat within the system to attack in order to maintain their sense of cohesion. At such times it is often the residents who are singled out to serve as scapegoats. Without a traditional hierarchy, a new power structure forms, with the resident often feeling that he is at the bottom. In fact, it seemed to me at times that this abuse was a kind of initiation rite covertly sanctioned by the ward chief. This rite involved tolerating ambiguity yet nurturing staff who rejected the need for support and direction. The ambiguity of the situation is illustrated by the following example: On one occasion a resident asked a nurse if she minded letting him take a patient out of her psychotherapy group for an hour in order for him to do a history and physical. She became angry and, when later confronted with her anger, said, "Just say you're taking a patient out of group. Don't ask." The resident must learn how to walk the fine line between the role of authority and that of trainee.

It generally takes several months for a resident to begin to grasp what is meant by participatory democracy, because in the first months he is adjusting to the surface issues that arise which reflect the more basic attitudes. Many residents never get beyond dealing with these issues and leave the ward feeling disappointed, angry, and inadequate; others withdraw from the learning experience. One such resident in my ward commented that he had felt as though he had been thrown into a lion's den and that he was daily nibbled away by the nurses and psychiatric technicians. It is interesting that a resident at the Yale Psychiatric Institute milieu unit made the identical comment about that system (5).

THE WARD CULTURE

The essence of this system, the concept of democracy, is an important ideal to the permanent staff, and from this system many staff members derive a substantial amount of self-esteem. In fact, many refer to the ward community as their "culture" and are extremely protective of it. Thus, when residents question what seem at times to be trivial issues, they often threaten certain members profoundly. To tolerate the experience and grow from it, the resident must be able to empathize with and make an honest attempt to understand the staff position.

The mechanism by which this or any other subculture arises and is maintained is a complex issue. People who are compatible with the system are purposely selected to work in it. They generally like this

system because 1) it validates their own philosophical beliefs, and 2) it is syntonic with their personalities. It is risky to make generalizations about staff personalities, but the following seem to be true: many of the staff can attain high status on this ward regardless of their level of training; in their personal lives they set a high value on spontaneity and informality, which are compatible with the ward's philosophy toward expressive therapies; and they often feel alienated from the mainstream of psychiatry and the competitive ideal of American culture and find common support of their "ideal" in this system. The ward chief under whom I worked was well-suited to this situation for several reasons. He was very much committed to the ideals of participatory democracy and was determined to run a humane system. At the same time, it was compatible with his personality to give up his personal authority in order to facilitate group responsibility. His personality and philosophical outlook were harmonious with the ward and, combined with his charisma, facilitated continuation of the "culture."

It may seem that participatory democracy and a milieu-oriented ward are synonymous, but a resident must learn that they are distinct. In adapting to the ward, a resident must grapple with problems he would face in any milieu. Participatory democracy is a logical philosophy to wed to a milieu-oriented ward but it must be understood as just that—a philosophy that can in fact be divorced from the system with which it is associated. The ward structure (milieu) is the vehicle of the philosophy (participatory democracy). Only residents but also nonmedical personnel experience feelings of alienation and isolation before being accepted as an integral part of the ward. But the resident, who is transient, often remains outside. Despite his attempts to adjust, he will move on while the permanent staff remain. He feels no less lonely if he realizes that only part of the problem is his own. In order to cope with this experience most residents rely on their supervisors, former residents from the ward, or their chief resident for support. Ironically, it is usually only by this method that a resident can gradually come to understand the ward, integrate the new values (if he chooses to), dissolve the barriers between staff groups, and finally incorporate himself into the system.

The Relationship of Community Mental Health Centers to the Professional Standards Review Organizations Program

BY O.B. TOWERY, M.D.

Given the realities of the professional standards review organization (PSRO) program and the necessity for accountability on the part of all health service providers, community mental health centers (CMHCs) should begin now to take an active role in planning their involvement in the PSRO program. The author points out the need for both psychiatrists and nonphysician professionals to become involved. There are many types of mental health services delivered in a given area, and the active involvement of CMHCs can be a major determinant of the shape and direction of this impact.

COMMUNITY MENTAL health centers (CMHCs) should begin now to actively plan their involvement in the professional standards review organization (PSRO) program. Although this program was authorized by amendments to the Social Security Act more than five years ago, until recently funding has been quite gradual. Physician groups in many PSRO areas had applied for planning grants, but there was little federal money available to support these efforts. However, recent funding appropriations for the support of local PSROs indicate that the program will rapidly become and remain the backbone of quality assurance activities nationwide. At this time PSROs are primarily focusing their efforts on the review of stays in acute, short-term general hospitals. Unlike many federal programs that are thoroughly conceived at the federal level and then implemented, the PSRO program is designed to evolve over the next several years, to experiment, and to establish policy based on whatever mechanisms seem to work well to assure quality care.

There are many ways in which PSRO review will have an impact on the types and quality of mental health services delivered in a given area, and it is hoped that the active involvement of CMHCs will be a major determinant of the shape and direction of this impact. The decision as to whether a particular admission will be paid for or will continue to be paid for beyond a certain point, as well as evaluations of the efficiency and effectiveness of the care given, will be made by either the PSRO itself or a delegated hospital committee. Clearly, the validity and usefulness of these determinations will depend on the degree of involvement by community mental health professionals.

The immediate emphasis of the PSRO program is on short-stay general hospitals and long-term care facilities, and direct involvement of mental health professionals in the review process is now limited to these levels of care. It will not be long, however, until PSROs begin to address ambulatory care. At that time PSRO policies and activities will have even greater consequences for the mental health care for which a CMHC is responsible. Even the functioning and fiscal viability of a center may be affected, especially if a national health insurance program with a broad range of mental health benefits is enacted.

Before considering the special situation of peer review of mental health services, it is necessary to briefly review the PSRO program and its functions.

PSROS

A PSRO is a voluntary, nonprofit professional organization representing a substantial proportion of the practicing physicians in a designated area. The PSRO must assure that health care provided to patients under the Medicare, Medicaid, and Maternal and Child Health programs is medically necessary and consistent with professionally recognized standards of care. Once a PSRO is operational (PSROs are accorded a "planning," "conditional," or "operational" status), the responsibilities currently held by Medicare contractors and Medicaid state agencies are relinquished to the PSRO. The PSRO's quality assurance program must be based on peer review and continuing education and must result in the improvement of quality, appropriate use of health care services, and continuing feedback about the effectiveness of the system.

A PSRO either performs or delegates to a hospital the responsibility of performing both concurrent and retrospective review. The purpose of concurrent review at present is to assure the necessity of admissions, the appropriateness of hospital stays, and the effectiveness of discharge planning. A PSRO or delegated hospital committee must also conduct medical

Dr. Towery is Special Assistant to the Director, Office of Program Planning and Evaluation, Alcohol, Drug Abuse, and Mental Health Administration, 5600 Fishers Lane, Rockville, Md. 20852.

The opinions expressed in this paper are those of the author and do not necessarily reflect the official policy of the Alcohol, Drug Abuse, and Mental Health Administration.

care evaluation studies, which are usually retrospective. The purpose of these studies is to identify deficiencies in the quality of health care and in the organization and administration of its delivery and to correct these deficiencies through education and administrative change. These studies are usually of short duration and focus on particular problem areas. Explicit criteria must be developed for objectifying the concurrent and retrospective review procedures and for screening purposes. In the future a PSRO will regularly analyze profiles on practitioners and patients in its area in order to identify deviations in the provision and utilization of services.

INVOLVEMENT OF NONPHYSICIANS

There are many important issues yet to be resolved that will affect the relationship of PSROs and CMHCs. One of the most important of these concerns the role of nonphysicians in the PSRO review process. A basic principle of the CMHC program from the beginning has been that the delivery of mental health services need not and should not be directed exclusively by psychiatrists. Many CMHCs do not even employ full-time psychiatrists or other physicians. In some ways it is unfortunate for CMHCs that the PSRO review methodologies are having their beginnings in the short-stay general hospital. Regulations developed for reviewing services at this level of care are concerned with physician-initiated care and thus appropriately delegate review authority almost exclusively to physicians.

However, in a CMHC many of the services that will come under PSRO scrutiny are delivered independently by nonphysician mental health professionals. Further, the blurring of roles that has occurred in many centers has resulted in a situation where a given service may be competently performed by several different professionals. For instance, an intake evaluation might be performed by a nurse, social worker, or psychologist. One implication of this is that within a CMHC representatives of several of the different mental health professions can and should contribute as a team to the reviews surrounding such activities. On the other hand, each of these professionals still has unique contributions to make in the treatment process. Thus, for example, criteria for appropriate placement after hospital discharge might best be developed by social workers. Each profession has its own limitations as well, and for that reason only professional peers can fairly decide whether a given clinical decision is appropriate. For example, the criteria for the appropriateness of obtaining a medical consultation might be different for a nurse than for a social worker, depending on the educational and experiential background of each.

The required statutory mechanism for the involvement of nonphysician health care practitioners in the PSRO program is the PSRO Advisory Group (1). The Advisory Group relates to either the statewide Professional Standards Review Council or [illegible] the PSRO, depending on whether or not [illegible] fewer than three PSROs and therefore does [illegible] statewide council. If there is a statewide [illegible] should seek assistance in assuring the [illegible] effective involvement of nonphysician health [illegible] titioners in each PSRO in such activities [illegible] ment of criteria and of review mechanisms [illegible] physician services and the review of [illegible] nonphysician peers (2). The council should [illegible] vice from the Advisory Group relating to [illegible] informational and liaison activities with [illegible] that represent nonphysician practitioners [illegible] facilities. The Advisory Group may also [illegible] statewide council in evaluating the per[illegible] state PSROs in areas relating to nonphysic[illegible]

If there is no statewide Professional S[illegible] view Council, the Advisory Group will [illegible] to the PSRO in many of the same ways that [illegible] the statewide council, assuring that nonphy[illegible] ticipate appropriately in the review proce[illegible] sory Group should also examine and com[illegible] review plans of hospitals regarding their [illegible] of nonphysicians.

As in other matters relating to PSROs, t[illegible] Groups' influence will to a large extent de[illegible] eral factors, not the least of which is the [illegible] nonphysicians and their organizations. [illegible] group will also be concerned with the PS[illegible] ship to the various health care facilities [illegible] behooves CMHCs to take an early activ[illegible] sure that their special concerns are not o[illegible] group made up of dentists, podiatrists, an[illegible] ministrators, for example, might very w[illegible] sent the interests of the nonphysician [illegible] professionals in a CMHC.

In terms of the review process itself, [illegible] practitioners should be involved in the de[illegible] most medical care evaluation studies, [illegible] CMHC where a team approach is used. [illegible] mittal, "Policies Applicable to PSROs [illegible] Health Care Practitioners Other Than [illegible] Peer Review in Short-Stay Hospitals" [illegible] this involvement when care provided [illegible] physicians is being reviewed.) Even wh[illegible] related primarily to care rendered by ph[illegible] as a study to evaluate the use of psychot[illegible] nurse or pharmacist might well contribut[illegible] spective which augments that of the psy[illegible]

Finally, nonphysician reviewers sho[illegible] tive role in the corrective actions taken [illegible] the review. If this involves continuing e[illegible] practitioners should take part in identif[illegible] oping educational mechanisms related [illegible] ty. If deficiencies in service are related [illegible] tive policy or resource allocation, appr[illegible] mendations should be made in these ar[illegible]

As indicated previously, PSROs are a[illegible] reviewing care in short-stay general hos[illegible] long-term care facilities. In most cases th[illegible]

affect the care given to the patients of a CMHC only when the CMHC's inpatient unit is in a general hospital or psychiatric hospital whose services fall under PSRO review. The PSRO program is now just beginning to direct itself toward the review of ambulatory care, and, with this, both the necessity and the opportunity for CMHC involvement will increase.

REVIEW OF AMBULATORY CARE

Thus far the description has been of PSROs as they are to conduct review of inpatient hospital services. Noninstitutional services are now being reviewed only in relation to demonstration projects. However, Public Law 95-142 (the recently enacted 1977 Medicare-Medicaid antifraud and abuse amendments) requires that PSROs will now have to address ambulatory care within two years of the time they become operational. Soon, the review of ambulatory services will take its place alongside inpatient review. Ideally, such review will be integrated to the point that the whole spectrum of care provided to any single individual can be evaluated as a total picture. This will permit a much more meaningful review, especially for CMHCs, since questions of appropriateness and necessity of one level of care are so often related to the availability and acceptability of other levels of care within the service system.

At this time it is impossible to predict what form PSRO review of ambulatory services will take, since sophisticated methodologies for such review have simply not yet been developed. Most of the review activities that have been developed relate to individual claims payment by third parties and are focused almost completely on efficiency and cost containment. Issues usually addressed are those of patient eligibility for coverage by a given plan, whether the services rendered are covered by the plan, and the appropriateness of the provider's charges. Patient and provider profiles, as well as office practice audits, have also been used to monitor quality in the ambulatory setting, but only to a limited extent (4).

Within a CMHC, as in other settings, there are many additional issues related to quality of care that must be addressed. Some of the principles and procedures developed for the inpatient setting will probably be relevant, but others will not. For example, the use of explicit criteria in review activities will probably remain an important requirement. Medical care evaluation studies, or some modification of these, are likely to be applicable to the ambulatory setting. The principle of correction by education and other principles related to appropriate utilization and follow-up of the review findings will also continue to be relevant. Procedures for peer review of services delivered by nonphysician mental health practitioners must continue to be an important part of the review system.

Two models for the review of services in CMHCs have already been developed and successfully implemented. At the Peninsula Hospital and Medical Center CMHC in Burlingame, Calif., three-member peer review committees meet weekly to review cases presented to them by therapists in person. In these sessions each case is discussed, and a course of therapy is agreed upon by the committee and the therapist (5). The Connecticut Community Mental Health Center in New Haven has developed a three-level approach to the review of services (6). Criteria relating to admission, assignment to group therapy, precautions against suicide, prescription of medication, and other aspects of the care given are first used by professional nonclinical reviewers for screening. Then peer reviewers examine selected cases and provide feedback on their findings. Other models, such as the routine peer review of prescribing patterns at the West Philadelphia Community Mental Health Consortium (7), have also been developed.

OTHER ISSUES

Other issues that must be resolved have to do with the nature of mental health care in general. Can we develop generally agreed-upon criteria that permit evaluation of all of the many types of mental health services delivered in a CHMC? Can we develop objective measures of progress and success for the many treatment goals that relate to complex intrapsychic changes and alterations in subjective experience? Can we develop review methodologies that meet the special needs of mental health, such as maximal preservation of therapist-client confidentiality and allowance for the legitimate variations in treatment length and intensity that derive from the different philosophies of treatment in mental health? Can we develop tolerance for the degree to which therapeutic success is dependent on factors beyond the therapy itself, such as client motivation? The answers to all of these questions must be affirmative if CMHCs are to relate successfully to the PSRO program.

CONCLUSIONS

Given the realities of the PSRO program and the necessity for accountability on the part of all health service providers, CMHCs should begin now to take an active role in determining their relationship to PSROs. Although there are still many areas in which PSROs have not been established or are only in the planning stage, many more PSROs will soon become operational. The development of the local PSRO should be attended to carefully, and both psychiatrists and nonphysician professionals should make every effort to become involved in the organization's review activities. An effort should be made to understand the policies and procedures of the PSRO program, which at times may seem difficult since many of the concepts of peer review and much of the language used are as yet

unfamiliar to many care providers. Developments at the national level should be closely followed.

In addition, centers should establish internal quality assurance mechanisms and develop the capacity to monitor themselves effectively. This is a requirement in the CMHC amendments of 1975 for all federally funded CMHCs, and a process should be undertaken by other centers as well. The review methodologies developed for general medicine and other specialties will not always be appropriate for mental health services, and usually those developed by mental health staff in a mental health setting will provide a more meaningful review process.

Borderline Diagnoses

BY CHARLES L. RICH, M.D.

The author describes the development of the borderline concept and the apparent inaccuracy of the original hypothetical framework. The signs and symptoms used to describe a "borderline syndrome" are often shared with other psychiatric illnesses. The author recommends that clinicians consider patients with only those features as "undiagnosed" until further research determines whether a distinct syndrome exists.

IT IS A COMMON and expected phenomenon for physicians to adopt and make use of catchall terms to cover their diagnostic limitations. Words such as "essential," "functional," and "idiopathic" are frequently found in the medical literature. They often describe symptoms or symptom complexes for [illegible] known of etiology, pathology, and/or [illegible] large the utilitarian purpose of such [illegible] ognized by the practicing physician. [illegible] aware, in essence, that he or she is saying [illegible] tient has an undiagnosed condition.

There are attendant risks when such [illegible] accepted as distinct diagnostic categories. A major risk is premature closure of diagnostic [illegible] leads to the application of such general [illegible] variety of other specific conditions that may [illegible] symptoms. This may deny patients potentially effective treatments. The problem of shared symptoms in the face of a shortage of confirmatory diagnostic laboratory tests) is one that plagues psychiatry as well. The word "borderline" has achieved substantial acceptance in psychiatry. This report discusses the development of the use of the word "borderline" from theoretical as well as practical standpoints. An attempt is made to define issues that have led to the confusion associated with the use of the word. Finally, an attempt is made to bring together information from several sources [illegible]

ing the so-called borderline syndrome to other studies of personality disorders.

THE HEALTHY-NEUROTIC-PSYCHOTIC CONTINUUM

One school of classifying psychiatric illness maintains (simply stated) that the various symptom complexes or syndromes are manifestations of a single psychopathological process that leads from health, through the neuroses, to psychosis. The syndromes are considered points on this continuum. Borderline patients are felt to comprise an unstable group that vacillates back and forth across the neurotic-psychotic boundary. Dickes (1) has argued (by analogy to other typical medical illnesses) that this single continuum concept is not accurate. He recommended abandoning the borderline concept as well as the terminology.

There is, indeed, systematic evidence pertinent to psychiatric illness that supports Dickes' stand. Studies comparing manic and schizophrenic patients (2) and depressive and schizophrenic patients (3) have shown qualitatively indistinguishable patterns of thought disorder in these otherwise clinically distinguishable syndromes. It has also been reported (4) that specific symptoms of psychosis (hallucinations) occur in several, more clearly defined syndromes (affective disorder, schizophrenia, Briquet's syndrome, organic brain syndromes, alcoholism), some of which are not usually considered psychotic. Finally, patients with schizophrenia, for whom the sine qua non is psychosis, are being seen more frequently sliding back and forth over that border as they are treated and then default from neuroleptic therapy and relapse (5).

It would seem, then, that the words "psychotic" and "nonpsychotic" (as opposed to "neurotic") may be useful clinical descriptors, but they should be used to modify rather than supplant more valid diagnostic categories. The evidence supports consideration of each syndrome as a separate entity, rather than as a point on a single continuum. It would also seem that research methodology should not attempt to compare "borderline" subjects to "neurotics" and "psychotics," since all three of these would appear to be unstable diagnostic labels.

MULTIPLE USES OF THE WORD "BORDERLINE"

A recent study (6) reviewed 20 patient charts that had been randomly selected for containing the word "borderline" in diagnostic terminology. It was found that 9 different borderline diagnoses were used. The diagnoses included borderline, borderline state, borderline personality, borderline syndrome, borderline psychosis, borderline schizophrenia, borderline schizoid personality, borderline hysterical character, and borderline character. Further, 7 of the 20 patients received 2 or more different borderline diagnoses; 5 received 2 such diagnoses and 2 received 3 borderline diagnoses.

This confusing and inconsistent clinical use of the word "borderline" has blossomed despite the fact that the only officially sanctioned use of the word is *DSM-II*'s "borderline mental retardation" (7). A second diagnostic framework devised for research purposes included "borderline features" as an adjectival modifier to another diagnosis, but not as a distinct syndrome (8). This has been recently changed to "schizotypal features," implying a closer relationship to schizophrenia than to the personality disorders (9). A recent preliminary draft of *DSM-III* does not include the word "borderline" anywhere, even in regard to mental retardation (10). It seems clear that the intent is to promote the use of more specific rather than general diagnostic terminology. This intent should be fostered, since psychiatry is under justified fire for its often casual approach to diagnosis. The addition of the word "borderline" to other diagnoses to denote atypical (as in "borderline features") and mild or, perhaps, incomplete (as in "borderline schizophrenia" [11]) forms of illness should be supplanted by the more specific adjectives.

EXCLUSION CRITERIA AND FOLLOW-UP STUDIES

Despite the loose clinical use of the word "borderline," its popularity suggests the possibility that there may be a common core of symptoms that clinicians and researchers are trying to describe and isolate. These signs and symptoms were initially studied by Grinker and associates (12). They were further refined by Gunderson (13), who, by using a semistructured interview, found five "summarizing statements" that significantly separated "borderlines" from both "neurotic depressives" and "schizophrenics." His study suffered from the shortcoming of starting with patients who had a certain clinical diagnosis of borderline despite the obvious lack of criteria for such certainty. In addition, Gunderson only excluded patients with evidence of organicity or a primary diagnosis of alcoholism or drug habituation, neurotic depression, and schizophrenia (the last two comprising the comparison groups).

Gunderson's summarizing statements, however, are quite similar to Small and associates' descriptions of patients with passive-aggressive personality (14) and Liss and associates' report of patients with undiagnosed personality disorders (15). The common clinical descriptions from all three studies included suicide attempts, drug abuse, manipulation, alcohol abuse, and anger. Liss and. associates were meticulous about systematically rediagnosing their patients both at initial inclusion and at follow-up (16). This excluded a number of patients who met the criteria for another, more well-established syndrome (17), again pointing out the necessity of providing rigorous exclusion cri-

teria in order to avoid as best as possible the shared symptom dilemma. Similarly, in a recent report (6) I found that 12 of the 20 patients who received some sort of borderline diagnosis met the criteria for some other illness as defined by Feighner and associates (17).

Despite their variation in quantity and quality, follow-up studies of patients with diagnoses of "borderline" (18), "passive-aggressive personality" (14), and "undiagnosed personality disorder" (16) suggest that there is a sizable group of such patients whose course is chronic and who remain characterized only by a persistence of the core signs and symptoms described by Gunderson (13). However, further studies aimed at better defining this possibly valid syndrome must pay scrupulous attention to excluding all other psychiatric syndromes because of the high frequency of shared symptoms. The approach necessary to do this has been outlined by Guze (19). It is also extremely important that clinicians pay scrupulous attention to ruling out other disorders that may be more treatable before assigning a patient to this group for which no effective treatment has been defined in controlled studies.

CONCLUSIONS

Research data suggest that the original basis for the borderline concept (i.e., the unitary health–neurosis–psychosis continuum hypothesis) is inaccurate. Loose and confusing clinical usage of the word "borderline" has moved it in the direction of clinical uselessness, which weighs in favor of dropping it from psychiatric nosology. This had wisely been done by the drafters of the proposed *DSM-III*. Gunderson (13) has devised inclusion criteria for a possibly valid syndrome. The high frequency with which these signs and symptoms are shared with a variety of other psychiatric illnesses makes systematic exclusion of those other illnesses imperative in further research. If there is validation of a distinct syndrome characterized by the signs and symptoms delineated by Gunderson, it should be assigned a neutral name (excluding "borderline") to avoid confusion with the multitude of other popular uses of the word. Until validation occurs, these patients should be considered "undiagnosed," as recommended by Hudgens (20). Finally, clinicians should remain alert that these signs and symptoms are frequently shared by other, possibly more treatable illnesses.

CLINICAL AND RESEARCH REPORTS

This section contains 1) new research findings, including preliminary data from pilot studies, either clinical or laboratory; 2) worthwhile replication studies; 3) case reports that describe a truly new syndrome or cast new light on established ones; and 4) case reports that indicate a new therapeutic procedure of potential value or call attention to adverse effects of drugs or previously unreported complications of therapeutic interventions. Program descriptions and literature reviews cannot be printed in this section. Criteria for format are listed in "Information for Contributors" in each issue; papers that do not adhere to these criteria will be returned to the author.

Drug History and Tardive Dyskinesia

BY ROBERT C. SMITH, M.D., PH.D., MICHAEL STRIZICH, AND DAVID KLASS, M.D.

Although there is a good deal of epidemiologic and experimental research clearly implicating neuroleptic drugs in the pathogenesis of tardive dyskinesia, it remains unclear whether any specific neuroleptics or dosage schedules contribute more strongly to the risk of tardive dyskinesia. This report presents preliminary findings from a study of drug history and tardive dyskinesia in chronically hospitalized mental patients.

Method

The subjects were 103 patients 50 years old and older selected for the drug-history study from a larger survey of tardive dyskinesia at Manteno State Hospital using stratified random sampling procedures based on tardive dyskinesia scores. Most patients were rated for tardive dyskinesia on at least two or three separate occasions with the Smith Tardive Dyskinesia Scale (described in part in previous publications [1, 2]); mean scores on a facial dyskinesia subscale are used in this report. The amount of neuroleptic drugs a patient had received over the entire period of hospitalization in the state system was quantified from medication records and doctors' orders. Because of changes in the procedures for medication records in the late 1960s, drug history records from 1968 on proved to be much more accurate; therefore, in this preliminary report, only post-1967 drug history data will be used. The amount of neuroleptics was measured both in grams and chlorpromazine equivalents (CPZ-E), using the conversion ratios of Davis (3). Correlations and partial correlations of several drug variables with mean facial dyskinesia scores are presented.

Results

Our analysis revealed that only one drug, fluphenazine, consistently had small to moderate positive correlations with tardive dyskinesia scores (see table 1). There was a much higher correlation when we separately examined the relationship between dyskinesia and the proportion of intramuscular fluphenazine a patient had received. In a small number of patients (N=12) who received any appreciable amount of intramuscular fluphenazine enanthate, the correlation between facial dyskinesia and proportion of neuroleptic medication given as fluphenazine was fairly high ($r=.70$, $p\approx.01$). The 5 patients in this group who had definite facial dyskinesia had received about twice as high a proportion of fluphenazine in their neuroleptic treatment (mean±SEM mg CPZ-E fluphenazine/g CPZ-E total neuroleptics=258±47) than patients with no signs or borderline signs of facial dyskinesia (mean fluphenazine=109±27), a statistically significant difference ($t=2.52$, $df=9$, $p<.05$). The total amount of thioridazine a patient had received tended to have a consistently small negative association with the dyskinesia score, although only some of these correlations were statistically significant. No other single drug had a consistent positive or negative association with the tardive dyskinesia score.

Contrary to our initial expectations, tardive dyskinesia was significantly negatively related to the total

††CPZ equivalence of total neuroleptics is controlled for in the original variable.

amount of neuroleptics that a patient had received. This finding held true when partial correlations were done to control for the amount of neuroleptic the patient received on the day of rating (partial correlation r=−.17, p<.05).

Discussion

Although our results suggest that one drug, fluphenazine, may be more toxic in regard to tardive dyskinesia, this conclusion should be regarded with caution because of several factors. First, all the patients had been treated with neuroleptic medications for many years and no patient had received only fluphenazine. Although we tried to control for some confounding factors by using partial correlations, it is still possible that a factor which was not controlled might account for the significant positive correlations with fluphenazine. Second, some patients who had not received substantial amounts of fluphenazine also had definite tardive dyskinesia. Third, in a single sample in which many correlations are computed, it is statistically possible to find a few significant correlations on a chance basis. Finally, our results on intramuscular fluphenazine, which showed the strongest relationship with tardive dyskinesia, are based on a small subsample.

It is important to note, however, that recently three other groups of investigators (4–6) studying the relationship of drug history to tardive dyskinesia found significant associations of tardive dyskinesia with intramuscular fluphenazine. We believe that additional work is now needed to determine whether these preliminary findings, based on research using retrospective methods, can be confirmed in more extensive prospective studies.

The fact that neuroleptic drugs are associated with tardive dyskinesia can lead to the idea that the higher the total amount of neuroleptics a patient has received the higher the risk or severity of tardive dyskinesia. However, when we reviewed the literature we found only one or two prior studies (7, 8) suggesting an association between the total amount of neuroleptic a patient had received and tardive dyskinesia. Patients who had received a relatively low total amount of neuroleptics (e.g., 1.5–112.5 g CPZ-E). [illegible] patients who had received far greater amounts of neuroleptics (up to 2500 g CPZ-E) found no relationship between total amount of neuroleptics and dyskinesia. The results of our study [illegible] the total amount of neuroleptic medication [illegible] has received over many years is not the [illegible] related to current tardive dyskinesia. We find a small positive correlation between the amount of neuroleptic that a patient received per year and tardive dyskinesia score (partial r=+.17). This correlation is very similar in direction and magnitude, to findings reported by Crane (10) that the maximum dose of neuroleptic was positively associated with tardive dyskinesia (correlation r=+.19). These results suggest that planning studies to investigate the relationship between neuroleptics and tardive dyskinesia it may be important to examine the schedule and consistency of neuroleptic administration rather than the total amount of medication a patient has received.

Filicide During Psychotropic-Induced Somnambulism: A Case Report

BY DANIEL J. LUCHINS, M.D., PAUL M. SHERWOOD, M.D., J. CHRISTIAN GILLIN, M.D., WALLACE B. MENDELSON, M.D., AND RICHARD JED WYATT, M.D.

In this paper, we report the case of a patient with drug-induced somnambulism who was studied in a sleep laboratory setting. To our knowledge, this is the first such report in the literature.

Case Report

The patient, Ms. A, is a 44-year-old woman with a history of one somnambulistic episode during adolescence but none after that until age 40. She also had enuresis until she was 16. There is no family history of somnambulism, enuresis, epilepsy, or psychiatric disorders. Ms. A was seen briefly by a psychiatrist when she was an adolescent for the enuresis and again in her 20s for anxiety subsequent to an unhappy love affair. She had no other psychiatric problems until she was 39, when she developed a florid psychosis with agitation and persecutory delusions. She was diagnosed as schizophrenic, hospitalized for 2 weeks, and treated with thioridazine, 25–100 mg q.i.d., with apparent recovery. A year later, she began to re-experience anxiety symptoms and resumed treatment on an outpatient basis. Because of insomnia, she received bedtime thioridazine and the hypnotic trichloroethanol (the active metabolite of chloral hydrate). Three months later, after taking both her bedtime thioridazine and a double dose of trichloroethanol, she arose from her bed at 3 a.m. and, apparently in a dissociated state, stabbed her daughter to death. When she was examined the next morning, she was found to be perplexed, hallucinating, and delusional, and was again diagnosed as schizophrenic. At her trial, she was acquitted by reason of insanity and hospitalized under court order.

With phenothiazines and psychotherapy, her psychosis slowly cleared. However, she was noted to sleepwalk 2–4 times a week. Diphenylhydantoin, 100 mg t.i.d., ethosuximide, 1250 mg q.d., and amitriptyline, 150 mg q.h.s., had no effect on her sleepwalking. Repeated EEGs, including one with nasopharyngeal leads, a pneumoencephalogram, and a CT scan revealed no abnormality.

Investigation

After four years in the hospital, Ms. A was transferred to a National Institute of Mental Health research ward at Saint Elizabeths Hospital for investigation of her somnambulism. Because she showed no evidence of active psychosis, either schizophrenic or affective, her medication (thioridazine, 300 mg q.h.s.) was discontinued. During a 1-month period, 11 all-night EEGs were carried out using conventional recording and scoring techniques along with continuous video monitoring (1). There were no sleepwalking episodes. She was then placed on thioridazine, 300 mg q.h.s., and chloral hydrate, 1000 mg q.h.s.—the same combination she took the night she killed her daughter. Episodes of somnambulism were recorded 3 out of 4 recording nights. Since she had been sleepwalking previously while she was taking only thioridazine, 300 mg q.h.s., she was again put on this regime and sleepwalked 1 of the 5 nights recorded. She was then briefly tried on chloral hydrate 2000 mg q.h.s., but did not sleepwalk on the 3 recording nights. A double-blind placebo trial was carried out. On placebo, there was no sleepwalking during 5 recording nights. On the first night of thioridazine, 300 mg q.h.s., and chloral hydrate, 1000 mg q.h.s., she sleepwalked. Table 1 summarizes the results of these investigations.

Sleep EEG Findings

The patient's sleep EEG had several unusual features. Both on and off medications she showed awakenings from stage 4 sleep in over half the nights, and many more brief episodes (5–15 seconds) of movements during stage 4. Also, regardless of medications, she had a short REM latency of about 30 minutes (49 minutes is about average).

All recorded episodes of sleepwalking occurred out of stage 4 sleep, which is consistent with other reports (2, 3). These episodes occurred during the first half of night, when stage 4 sleep is most prevalent. A feature which, to our knowledge, has not been noted previously is that at least one REM period elapsed before each episode.

In order to understand thioridazine's ability to induce sleepwalking in this patient, we compared sleep indices during 9 nights on thioridazine and 9 nights without thioridazine. Thioridazine significantly increased REM time (mean±SEM=103±19 minutes versus 82±21, $t=2.2$, $p<.05$, two-tailed test), and there was a suggestion of an increase in percentage REM sleep (28±3 versus 23±5, $t=1.89$, $p<.1$). There was also a suggestion of increases in total sleep time (385±30 minutes versus 348±49, $t=1.83$, $p<.1$) and stage 4 time (62±28 minutes versus 40±17, $t=1.88$, $p<.1$) on thioridazine.

Discussion

These findings indicate that Ms. A only sleepwalks while on certain psychotropic medications. We are aware of only three previous reports of drug-induced somnambulism. Christianson and Perry (4) reported two dermatologic patients who developed somnambulism on bedtime chloral hydrate. Huapaya (5) reported sleepwalking after bedtime methaqualone in two cases, chlorprothoxene in another, and a combination of

Dr. Luchins is Research Psychiatrist, Laboratory of Clinical Psychopharmacology, Division of Special Mental Health Research, Intramural Research Program, National Institute of Mental Health, Saint Elizabeths Hospital, Washington, D.C. 20032, where Dr. Gillin is Deputy Chief, Dr. Mendelson is Staff Psychiatrist, and Dr. Wyatt is Chief. Dr. Sherwood is Staff Psychiatrist, Institute of Living, 200 Retreat Ave., Hartford, Conn.

thioridazine and methaqualone in a fourth case. Flemenbaum (6), in the context of reporting several cases of pavor nocturnus (a stage 4 sleep abnormality) induced by large bedtime doses of neuroleptics and tricyclics, mentioned one case of somnambulism.

In all cases, the sleepwalking could be controlled by eliminating the offending substance totally, reducing its dose, or avoiding bedtime administration. Unfortunately, we did not have an opportunity to determine whether Ms. A would sleepwalk on daytime thioridazine.

In the one report in which data on childhood sleepwalking were available, sleepwalking was noted in two cases, sleeptalking in the third, and neither in the fourth (L. Huapaya, personal communication, 1978). Ms. A sleepwalked once in adolescence and also had a history of enuresis. Unfortunately, no data are available on a history of enuresis in the other cases.

Interpretation of the previously mentioned features of Ms. A's sleep EEG is difficult. We are not aware of other reports of frequent movement and awakening from stage 4 in patients with somnambulism or of the onset of somnambulism after at least one REM episode and the much shortened REM latency. The two latter findings might be related to each other but unrelated to somnambulism, since a decrease in REM latency is reported in schizophrenics in remission (7).

There was an indication that in the case of Ms. A, bedtime thioridazine may have increased REM and stage 4 sleep. Jus and associates (8) have reported increased REM and stage 4 sleep after large bedtime doses of neuroleptics but observed no such effect when the same dosages were administered in multiple daytime doses. Since somnambulism is a stage 4 phenomenon, it would be tempting to suggest that thioridazine's ability to induce sleepwalking is related to its action of increasing stage 4 sleep when given in large bedtime doses. However, this would not explain how methaqualone can induce sleepwalking, since this drug does not appear to increase stage 4 sleep (9).

The mechanism by which psychotropic drugs induce sleepwalking, therefore, remains obscure. It is possible that they interfere with an inhibitory system which normally prevents somnambulism. Future studies with "purer" pharmacologic agents may help elucidate such a system. For the present, administration of large bedtime doses of various psychot[illegible] with a history of sleepwalking (and, [illegible] stage 4 abnormalities) should be done [illegible].

Prediction of Self-Mutilation in Hospitalized Schizophrenics

BY DAVID SHORE, M.D., DOUGLAS J. ANDERSON, M.D., AND NEAL R. CUTLER, M.D.

We have recently seen several schizophrenic patients who injured themselves seriously during hospitalization on a locked inpatient ward. In each case no warning was identified before the self-mutilation. These events led to a search for predictive factors in order to develop a system approach capable of predicting and preventing self-injury in such patients.

Most of the literature dealing with prevention of self-injury has focused on psychotic children and the mentally retarded (1). There have also been a number of reports of self-injury in schizophrenics, described from a psychodynamic point of view (2–5). However, this literature only describes attempts to understand self-injurious behavior after the event or to control repeated episodes by behavior modification. To our knowledge, no one has developed a systematic method to identify which schizophrenic patients are at high risk for imminent injury.

Two examples of cases in which self-injurious behavior was not predicted and no specific preventive measures were taken are described below.

Case Reports

Case 1. A 46-year-old man was admitted to the hospital after inflicting superficial lacerations over much of his body with razor blades. The patient had an extensive psychiatric history and had been hospitalized in several VA hospitals, where he was diagnosed as having paranoid schizophrenia. At the referring hospital emergency room he stated that he was "the slasher" and that he still felt like hurting himself. On examination he was alert and oriented, with flat affect and loose associations. He denied homicidal or suicidal ideation, stating he did not know how the cuts had been made. He said someone else probably had cut him while he was asleep. During the first few days of hospitalization, the patient seemed preoccupied with auditory hallucinations. He told staff that he felt a great sense of personal guilt about world problems such as war and starvation. Later he attempted unsuccessfully to obtain a knife in order "to end it all," reiterating that he was "responsible for all sin." That evening the patient was found covered with blood. Both eyes had been enucleated. He later said that "a force" had overpowered him and taken control of his actions. He added that he had not feared the motives of this force.

Case 2. A 39-year-old man with a history of paranoid schizophrenia came to the hospital complaining of hearing confusing voices. He stated that he had been "under satanic attack" for several weeks and that people were out to get him. He had cut his forearm and neck seriously 24 hours before admission. At the time of examination he denied suicidal ideation and was calm and cooperative at all times. During his first day on the ward the patient appeared to be in good spirits and no longer reported the experience of a spiritual or moral struggle. Subsequently, however, he was found with a pencil through the inner canthus of his right eye. He stated that he had done this because "The Lord says, 'If thy right eye offend thee, then pluck it out.' " He added that he communicated to others through his eyes and that he was worried that others might thereby learn his secret thoughts. The patient was placed in restraints and tranquilized with neuroleptics over the next several days. Six days later he stated that he felt he had done "a stupid thing," that he "must have misconstrued the spiritual meanings." The patient exhibited no further self-injurious behavior during his stay.

Discussion

The two patients we have described had histories or obvious evidence of prior self-injury. In addition, both were outwardly calm preceding the event. One patient gave evidence of self-referential religious preoccupation, and the other believed he was under the control of a trusted outside force. All of the cases of self-injurious schizophrenics that we have seen have shared these features. We have also discovered other cases in the literature that fit this pattern (2–6).

Simultaneous with our study three investigators, (J.E. Crowder, C.A. Gross, and J.E. Heisen) accumulated a series of six cases of self-mutilation of the eye (unpublished data). Their findings are consistent with ours in that five of their patients had histories of previous self-injury, and all six had tyrannical consciences (usually with religious preoccupation). All six revealed guilt feelings displaced to the eye and all experienced a sense of relief from anxiety in the attempted self-enucleation.[1]

System Approach

We recommend the following approach to the hospitalized schizophrenic patient in order to assess the risk of imminent self-injury. The patient should be questioned and examined for history or evidence of pre-

Drs. Shore and Anderson are Assistant Clinical Professors of Psychiatry and Human Behavior, University of California, Irvine, where Dr. Cutler was Resident in Psychiatry when this work was done. Dr. Cutler is now Staff Psychiatrist, Section of Psychobiology, Biological Psychiatry Branch, National Institute of Mental Health, Rockville, Md. When this work was done, Dr. Shore was also Staff Psychiatrist, Long Beach Veterans Administration Hospital, Long Beach, Calif.; he is now Staff Fellow, Laboratory of Clinical Psychopharmacology, National Institute of Mental Health, St. Elizabeths Hospital, Washington, D.C. Dr. Anderson is also Staff Psychiatrist, Long Beach VA Hospital, 116A, Long Beach, Calif. 90822.

The authors wish to thank Philip Cohen, M.D., John Crowder, M.D., G. Globus, M.D., and E. Mansell Pattison, M.D., for their helpful comments.

[1]Of the six patients in the Crowder and associates study, five were clearly or probably schizophrenic, and the sixth was diagnosed as a psychotic depressive with religious preoccupation and auditory command hallucinations.

vious self-injury. He should also be carefully examined for concrete religious preoccupation, for presence of auditory command hallucinations, and for delusions of reference or of control by outside forces. Careful questioning is then necessary to determine whether the patient trusts his concrete preoccupations, command hallucinations, or delusions. Patients who do not have this trust will often appear anxious and ask for relief from their torment. However, if the delusions and/or hallucinations are trusted, patients may appear outwardly calm. Just as the depressed suicidal patient who shows an elevation of mood and lack of distress may have finally resolved to kill himself, the schizophrenic patient, torn between the forces of God and the devil, may display outward calm, having decided upon the sacrifice of some part of his body for his greater spiritual good. The Bible tells us, "Better for part of you to be destroyed than for all of you to be cast into Hell."

We believe these outwardly calm patients present the greatest risk of self-mutilation, and we recommend rapid parenteral tranquilization as the treatment of choice. Such patients should be kept under constant observation until the rapid tranquilization brings the psychotic symptoms under control or until sedation supervenes. We consider the risks of rapid tranquilization as described by Ayd and others (7–9) to be minimal when compared with the risk of self-mutilation. When these patients are no longer psychotic, they usually regret their self-injurious behavior, saying, for example, "I misinterpreted the Bible and took it literally instead of metaphysically" (3).

Conclusions

No one can predict self-injurious behav[illegible] absolute certainty. Based on clinical exper[illegible] ever, we have proposed a method to dete[illegible] schizophrenic patients present an acute [illegible] episodes. When such a risk is establishe[illegible] quilization is recommended because it is [illegible] and can prevent self-injury. Our experie[illegible] method is encouraging. Since the gener[illegible] this system approach at our hospital, we [illegible] further episodes of serious self-injury a[illegible] ized schizophrenics.

Anticholinergic Delirium in a Case of Munchausen Syndrome

BY MARC H. HOLLENDER, M.D., ROBERT C. JAMIESON, M.D., EMBRY A. MCKEE, M.D., AND HOWARD B. ROBACK, PH.D.

Atropine delirium resulting from the use of eye drops has been reported, usually in letters to the editor, for nearly a century (1). In almost all instances the medication had been used to prepare for a refraction or to treat an eye disease. In only one article was accidental exposure mentioned (2). The case we will report is unique in that an atropine-like substance was self-administered with the intention of producing dilated pupils to simulate a neurologic disorder[illegible] which was not expected by the patient, w[illegible] ric disorder (delirium).

Mention in psychiatric texts of atropine [illegible] sulting from eye drops is seldom more th[illegible] comment. Levin (3) stated in the *Americ[illegible] of Psychiatry*, "Poisoning can occur eve[illegible] doses [of atropine], such as those used [illegible] pupils." Chapman (4) noted, "Children [illegible] develop brief organic brain reactions after [illegible] of atropine in the eye." In the *Compre[illegible] book of Psychiatry*, Linn (5, p. 807) states [illegible] and its derivatives may cause characteristi[illegible]

The authors are with the Department of Psychiatry, School of Medicine, Vanderbilt University, Nashville, Tenn. 37232, where Dr. Hollender is Professor and Chairman, Dr. Jamieson is Co-Chief Resident, Dr. McKee is Assistant Professor, and Dr. Roback is Professor (Psychology).

hallucinations in drug-sensitive adults receiving relatively small quantities in the form of eyedrops . . . ." In the same textbook, Peterson (5, p. 1114) noted, "Solutions of these agents [piperidine derivatives] are also widely used in ophthalmology. . . . These solutions may be swallowed in the tears by way of the nasolacrimal duct and produce anticholinergic intoxication."

In our search of periodicals, we found cases of atropine delirium resulting from eye drops cited in general medical, ophthalmologic, and pediatric journals, but not in psychiatric publications. Although psychiatrists are sometimes called on to treat this disorder, they seem less well acquainted with it than some other specialists. Kounis (6) commented, "Atropine . . . contributes more frequently than is appreciated, and in smaller doses than is believed, to . . . the atropine eyedrop delirium." Hopkins and Robyns-Jones (7) stated, "We are told by ophthalmologists that . . . delirious states associated with atropine administration are not uncommon." It has been suggested that mild mental disturbances following eye surgery "attributed to emotional stress of the post-operative regimen may be due in part to atropine intoxication" (8).

In recent years various atropine-like postsynaptic blockers have been substituted for atropine sulfate in the practice of ophthalmology. In addition, as in the case we will report, other anticholinergic medications may be used systemically, producing an additive effect. It seems appropriate, therefore, to speak of an anticholinergic delirium rather than an atropine delirium.

Case Report

Ms. A, a 28-year-old licensed practical nurse, came to the emergency room of Vanderbilt University Hospital late one evening stating that she began to experience frightening visual and auditory hallucinations a half an hour after taking two tablets of a proprietary medication (Sominex). The visual hallucinations were of bugs, dogs, long black snakes coming out of faucets, and laughing faces in cups of coffee, and the auditory hallucinations were of voices telling her how horrible her life situation was. She seemed to be disoriented to time, place, and person. (Subsequently, it was learned that, in addition to the Sominex, she had taken chlorpromazine, 200 mg, and amitriptyline, 150 mg.)

When seen in the emergency room, Ms. A was wearing a neck brace and a cast on her left forearm. She claimed to have broken her left radius and sprained her neck in a car accident. (During subsequent interviews, she reported first that her ulna was fractured, then that the radius and ulna were fractured, and still later that the fracture included the radius, ulna, and metacarpals.) X rays of the left forearm revealed no evidence of fractures, and the police had no record of a car accident in which she had been involved.

On physical examination Ms. A's pulse was rapid (116 beats per minute), and her pupils were markedly dilated and fixed. The pupils did not constrict in response to the application of 1% pilocarpine eye drops. Based on the clinical findings, the internist and neurosurgeon who examined her concluded that Ms. A was delirious. She was then referred to a psychiatrist who admitted her to the psychiatry unit.

Ms. A, previously diagnosed as having Munchausen syndrome, had had numerous hospital admissions in Nashville and elsewhere. She had at various times consulted many specialists—ophthalmologists, internists, neurologists, neurosurgeons, endocrinologists, orthopedic surgeons, and psychiatrists—for her "illnesses."

Soon after this admission to the psychiatric unit Ms. A had a seizure, presumably psychogenic. She was informed that in view of extensive neurologic studies in the past, no additional studies were planned. No other seizures occurred during this hospital stay.

Two bottles of tropicamide (Mydriacyl), a short-acting mydriatic, were found in Ms. A's hospital room. She was told that dilated pupils which did not respond to pilocarpine could only be due to eye drops and that she must be responsible for the pathological finding. Initially, she denied using eye drops, but she soon broke into tears and acknowledged that she had. Following discontinuation of the medication her pupils gradually returned to normal, but the hallucinations persisted for 2 weeks.

Comment

It is well known that atropine eye drops can produce delirium but less well known that delirium can appear with few or no significant peripheral signs of intoxication (7). In Ms. A's case the only physical signs were rapid pulse and dilated pupils. The old description of atropine intoxication—hot as a hare, red as a beet, dry as a bone, blind as a bat, and mad as a wet hen—applied only in part to her.

Cases of delirium have been ascribed to "inherent susceptibility to the drug" or to "idiosyncratic susceptibility." In other instances the large amount of the medication absorbed (one drop of the 1% solution contains 0.75 mg of atropine) probably reached a toxic level. Atropine eye drops are carried to the nasal mucosa and intestinal tract mixed with tears via the nasolacrimal ducts. How much eye medication Ms. A used is not known, but it is known that she did not exert pressure on the inner canthus of the eyes to prevent fluid from passing through the nasolacrimal ducts.

Although mention is made of special susceptibility to atropine delirium in the very young and the aged, many reported cases are in middle-aged patients. The age range is from early childhood to 82 years, and no age is spared.

The clinical picture may resemble delirium tremens because of visual hallucinations of insects and animals, as in Ms. A's case. Restlessness, fearfulness, agitation, confusion, and fever are commonly reported. Much less often there may be paranoid delusions and some resemblance to schizophrenia.

In most instances, discontinuation of the eye drops has resulted in the relief or disappearance of all symptoms of atropine intoxication in 6 to 48 hours. In only a few instances have the symptoms subsided in less than 6 hours or persisted for more than 48 hours. The diagnosis of atropine delirium has been confirmed by injection of small doses of atropine to reproduce the disorder (8, 9).

To differentiate pupillary change produced by eye

drops from neurologic disease, pilocarpine, a parasympathomimetic agent, is safe and reliable. It causes constriction of the iris sphincter unless atropine or another postsynaptic blocker, such as tropicamide, the substance involved in this case, has been used.

Physostigmine salicylate (Antilirium) was not used, but it is effective in treating anticholinergic intoxication when administered intramuscularly (1 mg repeated in 15–20 minutes if necessary).

In Ms. A's case, the anticholinergic effects of chlorpromazine, amitriptyline, scopolamine (Sominex) (10), and tropicamide were probably additive.

Although her disorientation cleared rapidly, Ms. A maintained that her hallucinations persisted during her 2-week hospitalization. However, it is difficult to know whether this was actually the case. Given the previous diagnosis of Munchausen syndrome and her unusual willingness to assume the psychiatric patient role as well as the medical-surgical patient role, it is not unlikely that she was attempting to prolong her hospitalization.

Neuroleptic-Induced Supersensitivity Psychosis

BY GUY CHOUINARD, M.D., M.SC. (PHARMACOL), BARRY D. JONES, M.D., AND LAWRENCE ANNABLE, DIP. STAT.

Dopamine receptor binding sites have been reported to increase in the neostriatum after chronic treatment with neuroleptics, which could account for the dopamine hypersensitivity that induces tardive dyskinesia (1). We propose that similar changes may occur in the mesolimbic region in response to the chronic dopamine blockade of these drugs. Three kinds of clinical evidence are compatible with this hypothesis: 1) central nervous system (CNS) drug tolerance; 2) psychosis following neuroleptic withdrawal, which is correlated with signs of dopamine supersensitivity and which we would therefore term "supersensitivity psychosis"; and 3) psychosis associated with a sudden decrease in prolactin levels following neuroleptic withdrawal.

Study Reports

CNS drug tolerance. In a double-blind controlled study we compared fluphenazine enanthate given every 2 weeks with fluphenazine decanoate given every [illegible] maintenance treatment of 48 schizophrer[illegible] Before entering the trial, patients had rece[illegible] enanthate routinely for periods of 1 to 12 [illegible] 14). All patients underwent a further 1-mo[illegible] lization with fluphenazine enanthate. The [illegible] of the fluphenazine enanthate-treated pa[illegible] the trial ranged from 2.5 to 125 mg (medi[illegible] 39.3 mg) and after 7 months of treatment [illegible] 325 mg (median=50 mg, mean=69.1 mg). [illegible] increases in dosage were required to ma[illegible] therapeutic effect at the same level. In an[illegible] longed exposure to neuroleptics leads to [illegible] requirements to block the behavioral effec[illegible] (3, 4).

Psychosis associated with signs of [illegible] sensitivity. In a 6-week double-blind tria[illegible] serazide we studied the relationship betw[illegible] nesia and psychotic relapse in 32 patients [illegible] ophrenia (5). Half of the subjects rec[illegible] benserazide instead of their regular neu[illegible] and half received chlorpromazine. In the [illegible] the severity of tardive dyskinesia (assessed [illegible] ical impression scale of the Extrapyramid[illegible] Scale [2]) tended to be greater in the 8 pa[illegible] rated than in the 6 patients who did [illegible] 5.4±1.4 and 3.8±1.7, respectively, t=1.[illegible] ever, there was no difference in severity [illegible] nesia between the deteriorated (N=2) a[illegible] (N=14) chlorpromazine patients (means [illegible]

Dr. Chouinard is Assistant Professor of Psychiatry, McGill University, and Psychiatrist, Research Department, Hôpital Louis-H. Lafontaine, 7401 rue Hochelaga, Montreal, Que., Canada H1N 3M5. He is also Professor, Institut National de la Recherche Scientifique-Santé, where Mr. Annable is Biostatistician. Dr. Jones is Resident, Department of Psychiatry, McGill University, where Mr. Annable is Assistant Professor.

The authors wish to thank Ms. Marilyn E. Levy for her assistance.

0002-953X/78/0011-1409$0.35 © 1978 American Psychiatric Association

3.9±1.9, respectively) or between the nondeteriorated patients in the two drug groups.

These results are consistent with the hypothesis that the relationship between severity of tardive dyskinesia and psychotic decompensation may be due to a common underlying mechanism of increased dopaminergic function covertly induced by long-term use of neuroleptics and made overt by drug discontinuation. There was no evidence that increased agitation caused a worsening of tardive dyskinesia, since the 2 deteriorated chlorpromazine patients did not show signs of having more severe tardive dyskinesia than the nondeteriorated tryptophan-benserazide patients.

Psychosis associated with sudden decline in prolactin levels. In a pilot study designed to test whether penicillin has an antipsychotic effect, 10 hospitalized schizophrenic patients chronically treated with neuroleptics had their medication withdrawn and replaced with oral penicillin for 6 weeks (6). Greater decreases in prolactin (geometric mean=22.6 ng/ml, range=11.7–51.7 ng/ml on day 0; geometric mean=6.0 ng/ml, range=3.7–10.3 ng/ml on day 42) tended to be associated ($r=.62$, $df=6$, $p<.10$) with symptomatic deterioration (mean BPRS total scores ±SD=37.5±8.8 on day 0 and 46.1±13.2 on day 42), and increased severity of tardive dyskinesia was significantly correlated with decreases in prolactin ($r=0.85$, $df=6$, $p<.01$).

There is evidence to suggest that supersensitivity does not occur in response to chronic dopamine blockade in the dopamine hypothalamoinfundibulum tract (7), so the extent of prolactin elevation can be seen as a measure of absolute dopamine blocking. That some patients require more dopamine blocking to control their symptoms, as suggested by their elevated prolactin levels, and relapse suddenly when the dopamine blocking is removed is consistent with the hypothesis that these patients have developed a supersensitivity in their mesolimbic dopamine receptor sites as they have in the neostriatum.

Discussion

The association between dyskinesia and psychotic relapse has been observed by others (8, 9). The hypothesis that tardive dyskinesia and supersensitivity psychosis may be caused by a similar mechanism occurring in different areas of the brain is suggested by the common factors that can alter the clinical picture of both syndromes: increasing the neuroleptic dosage decreases the severity of dyskinesia and psychosis, decreasing the dosage makes both worse, stress exacerbates both dyskinetic and psychotic symptoms, and L-dopa and amphetamine can increase the severity of both.

We suggest that neuroleptics can produce a dopamine supersensitivity that leads to both dyskinetic and psychotic symptoms. An implication is that the tendency toward psychotic relapse in a patient who has developed such a supersensitivity is determined by more than just the normal course of the illness. This may explain why Hogarty and associates (10) were unable to identify "good prognosis" patients who do not relapse when maintenance neuroleptics are discontinued.

Another implication is the possibility that this supersensitivity is irreversible. This is accepted to be true of tardive dyskinesia unless it is diagnosed early and medication is discontinued. If the same irreversibility is occurring in the mesolimbic region, the result would be patients who must remain on neuroleptics for the rest of their life regardless of the natural course of their illness. In the studies done by Hogarty's group, two-thirds of patients thought to be suitable for drug withdrawal after 2 years of drug therapy relapsed following drug discontinuation, causing the authors to state that "the need for maintenance chemotherapy may be indefinite" (10). In some of these cases, the need for continued neuroleptic treatment may itself be drug-induced.

Tricyclic Overdose in a Patient Given Combined Tricyclic-MAOI Treatment

BY KERRIN WHITE, M.D

Recent reviews have documented the safety of combining monoamine oxidase inhibitors (MAOIs) and tricyclic antidepressants, particularly if one avoids parenteral medications, use of imipramine, or the delayed addition of tricyclics to established MAOI treatment (1–3). Reported overdoses have formed part of the "evidence" against use of tricyclic-MAOI combinations (4–8). Reviewing fatal versus nonfatal overdoses involving both MAOIs and tricyclics, Ananth and Luchins (3) remarked, "In none of the non-fatal overdose cases was the patient on a course of MAOIs before taking the tricyclics." In this paper I will describe such a case, in part to offset the alarm evoked by earlier reports, since fear of fatal reactions has prevented controlled research in this area for too long.

Case Report

A 21-year-old man was admitted with the chief complaint of hearing the voice of a dead friend telling him to kill himself. For the previous 6 months, after the death of this friend, he had been intermittently depressed and suicidal and had received chlorpromazine and amitriptyline in day care and in one previous psychiatric hospitalization. A few weeks before this admission, he stopped treatment, suffered fitful sleeping and a 9.1-kg weight loss, and began to hallucinate. When he was admitted he appeared depressed, hostile, and suicidal. Physician examination revealed no pathology other than obesity and chronic bronchitis. Complete blood count, serum electrolytes, and serum liver function tests were all essentially normal.

In part because of his history of poor response to amitriptyline, he was started on tranylcypromine, 10 mg q.a.m., and doxepin, 50 mg q.h.s.; gradually increased to tranylcypromine, 20 mg at 6:00 p.m., and doxepin, 150 mg q.h.s. He complained mainly of drowsiness and dry mouth but also had a stiff neck (relieved by diazepam), nausea, and vomiting. Blood pressure, recorded daily, never rose above 140/100. After 17 days on this treatment, he began to improve, and 17 days later he was discharged with a 2-week supply of both medications.

Two days after his discharge, the police found him unconscious. He had made a suicide attempt by overdosing on an unknown quantity of doxepin. He later persistently denied memory of the events immediately preceding his overdose. When he was first examined by paramedics, his pulse rate was 110 per minute, respiratory rate 40 per minute, and blood pressure 114/80. His pupils were equal and constricted, with slow response to light and dysconjugate gaze. On admission to our medical unit, within 3 hours after the police found him, he was lavaged and pink capsules were recovered. Pulse rate was 110 and regular, respirations were 36 and regular, blood pressure was 130/72 and his temperature was 98°. He was described as being in [illegible] i.e., purposefully responsive to painful stimuli [illegible] peared flushed, especially over the lower ex[illegible] flexes were normal. An ECG showed right [illegible] block. A complete blood count was normal [illegible] vated white count (14,800), serum electrolytes [illegible] except for elevated uric acid (8.3), and serum [illegible] tests were normal except for elevated creatin[illegible] nase (810). The patient awoke the next day, [illegible] otherwise without adverse after-effects and [illegible] abnormality.

Discussion

This patient, after more than a mont[illegible] tricyclic-MAOI treatment overdosed o[illegible] and presented a clinical picture consisten[illegible] tricyclic overdose. No hypertension, hyp[illegible] seizures occurred. This observation cont[illegible] few catastrophic case reports of similar c[illegible] ations, which have contributed to the pic[illegible] combination therapy. It seems significa[illegible] cyclic overdose occurred in a patient o[illegible] MAOI reputed to be most dangerous[illegible] mine. On the other hand, this overdose i[illegible] pin, a drug not (to my knowledge) pre[illegible] cated in presumed adverse reactions to[illegible] therapy. Although part of the explanation [illegible] more recent introduction of doxepin, thi[illegible] tainly been combined with MAOIs be[illegible] denced by Ayd's survey (9) of 55 such ca[illegible] ently without untoward effect. Perhaps [illegible] supersede amitriptyline as a drug of cho[illegible] nation with MAOIs.

Although this one case cannot prove th[illegible] bination therapy poses no special risks to [illegible] overdose, it is encouraging to those inte[illegible] bination therapy to know that one such [illegible] curred without unusual consequences [illegible] pay attention to the rare disaster while [illegible] the less dramatic, more commonplace co[illegible]

Social Adjustment in Primary Affective Disorder

BY DAVID L. DUNNER, M.D., GERARD J. IGEL, AND RONALD R. FIEVE, M.D.

The purpose of this paper is to assess social adjustment in patients with primary affective disorder. Recently, Weissman and Paykel (1) studied social adjustment in depressed patients using a structured questionnaire—the Social Adjustment Scale—derived from an interview used by Gurland and associates (2). Their studies showed that the women depressives had worse adjustment in several social areas when they were depressed than when euthymic, and that euthymic depressed patients showed worse social adjustment than controls. The population studied by Weissman and Paykel was described as having primarily unipolar depression.

We have administered a self-report version of the Social Adjustment Scale (SAS-SR) to patients attending an outpatient lithium clinic (3). Our major interests were to describe the social adjustment states of these patients, most of whom had bipolar depression, and to compare data on the depressed women in our sample with the data reported by Weissman and Paykel.

Method

The study was conducted in the lithium clinic of the New York State Psychiatric Institute. All 169 subjects met the diagnostic criteria of Feighner and associates (4) for primary affective disorder and were further classified into bipolar and unipolar subtypes (5). Patients termed bipolar I had been hospitalized for mania at least once. Bipolar II patients had been hospitalized for depression only and had histories of hypomania. Patients termed "bipolar other" had never been hospitalized for affective disorder but had received outpatient treatment for depression and hypomania. Patients were classified as unipolar if they had been hospitalized or treated for depression and had no history of mania or hypomania.

All patients participated in the study voluntarily. Each patient was asked to complete the SAS-SR for the 2-week period preceding the clinic visit. This questionnaire consists of several questions in 6 areas of social adjustment (work, spare time, extended family, marital, parental, and family unit). The questions are each scored on a 5-point scale, with 1 representing excellent adjustment and 5 poorest adjustment. We obtained mean scores for each area and for the questionnaire overall. Patients were instructed on filling out the questionnaire by one of us (G.I.), and the questionnaire was reviewed for completeness of response.

At each clinic visit, the patient's mood was assessed by a trained nurse or psychiatrist (6). Mood ratings were assessed independently of social adjustment data. Most of the patients in this study were treated on an open or double-blind basis with lithium carbonate.

Results

The breakdown of this sample by diagnosis and sex is presented in table 1. The overall mean adjustment scores for these patients did not differ significantly by diagnostic group or by sex. These overall means were about 2, indicating good but not optimum adjustment.

The data were further analyzed by separating patients into euthymic and noneuthymic groups. Most of the noneuthymic patients were mildly depressed, and noneuthymic patients had higher mean scores (worse adjustment) than euthymic patients in most areas of social adjustment. When patients were separated by median age, younger patients had worse adjustment in work, spare time, and extended family. No significant differences emerged when the data from our younger women were compared with the SAS-SR data from Weissman and Bothwell (7). Weissman had evaluated the SAS-SR in a sample of up to 327 residents of the New Haven community (personal communication) and found that the mean values of the six social areas ranged from 1.3 to 1.9. Our 115 euthymic patients showed slightly higher mean scores, but these were within 1 standard deviation of the community controls.

Revised version of a paper presented at the VI World Congress of Psychiatry, Honolulu, Hawaii, Aug. 28–Sept. 3, 1977.

TABLE 1
SAS-SR Scores by Sex and Diagnosis

Diagnosis	N	Age (years) Mean	Age (years) SD	SAS-SR Overall Score Mean	SAS-SR Overall Score SD
Bipolar I					
Men	31	46.4	13.3	1.82	.50
Women	43	43.3	14.5	1.90	.44
Bipolar II					
Men	20	50.9	14.2	1.87	.49
Women	26	53.5	12.6	1.96	.45
Bipolar other					
Men	9	42.0	13.7	2.20	.54
Women	14	38.4	12.8	2.15	.64
Unipolar					
Men	11	48.3	14.5	2.12	.67
Women	15	46.4	15.2	2.14	.53

Discussion

Our study, like those of Weissman and coworkers (1, 7), shows that age, sex, and mood state affect ratings of social adjustment. Age of subjects appeared to have less effect than mental state. Our younger bipolar I women patients showed lower (i.e., better) SAS-SR ratings in each social area compared with the Weissman and Bothwell sample of depressed women, and it is possible that the stabilization of mood disorder in this bipolar group resulted in improved social adjustment.

The community survey data, which were supplied to us by Weissman, indicate control subjects generally have mean scores of approximately 1.5 in each social area, with standard deviations of approximately 0.4. Thus, most of the control sample scored each question 1 (perfect adjustment) or 2 (slight problems). For our total sample (including noneuthymic patients), the overall means for the various diagnostic groups were ≈2.0, and standard deviations were ≈0.5. Since differences between controls and patients are slight, it is possible that further improvement in social [illegible] could not be assessed in these patients by [illegible] SAS-SR.

Weissman and associates (1, 7) have [illegible] their data as suggesting that depressives [illegible] measurable social impairment that improves with [illegible] They suggest that patients may have residual social impairment although symptomatically improved, and that psychotherapy (in combination with medication) may be of additional value [illegible] persistent social dysfunction. It is not clear [illegible] that patients whose moods have been stabilized with medication could show significant improvement in social adjustment, at least as measured by the SAS-SR. Our data do not suggest that there are consistent meaningful impairments in social functioning in euthymic patients sufficient to justify initial and maintenance treatment with psychotherapy. We suggest that patients with primary affective disorder can usually be well stabilized with medication alone and that psychotherapy (in addition to medication) should be employed only when the patient is clearly impaired in specific social areas.

Laryngeal-Pharyngeal Dystonia as a Possible Cause of Asphyxia with Haloperidol Treatment

BY JOSEPH A. FLAHERTY, M.D., AND HENRY W. LAHMEYER, M.D.

Numerous case reports have associated sudden death with the use of phenothiazines. There has been speculation that these deaths were caused by seizures and asphyxiation, but recent literature has emphasized the cardiovascular causes (1).

We have recently seen several patients with respiratory distress associated with the use of the nonphenothiazine antipsychotic haloperidol whose symptoms were relieved by diphenhydramine. We will present two illustrative cases and discuss the possible association with the phenothiazine-related sudden deaths.

Case Reports

Case 1. Mr. A., a 28 year-old man, was admitted complaining of auditory hallucinations and external control. Examination revealed loose associations, suspiciousness, and paranoid delusions. Results of a physical examination were normal, as were urinalysis, blood chemistries, and a drug screen. He was started on 10 mg of haloperidol on day 4, and the dosage was increased to 20 mg/day 3 days later. He was improving symptomatically until day 10, when at 7:00 a.m. the nurse found him in bed making agonized gestures and noises and pointing to his throat. Although the respiratory rate was normal, the pulse was 96. The nurse thought he was having trouble breathing or swallowing. One of us (J.F.) arrived about 7:15 a.m. and saw the patient immediately. His skin and nail color was mildly cyanotic, auscultation revealed some upper airway sounds, and breathing was normal except for some intraclavicular retractions. Throat examination seemed normal, except for some collection of secretions and an absent gag reflex. The patient seemed extremely anxious. He was given 50 mg of diphenhydramine I.V. slowly and resumed normal breathing and relaxed immediately thereafter. No other dystonic or extrapyramidal symptoms were noted, and an otolaryngological exam later that day was unremarkable. Because of the possibility that this was a dystonic phenomenon, he was given 2 mg/day of benztropine during the next 2 weeks. No further dystonic phenomena were noted for the duration of the patient's stay (29 days). He had normal course of hospitalization, with a remission of the acute schizophrenic symptoms.

Case 2. Mr. B, a 39-year-old man with a history of four psychiatric hospitalizations for schizophrenia, was admitted with acute schizophrenic symptoms. He had not been taking antipsychotics. A drug screen was negative, and results of a physical examination were normal. He was started on haloperidol, 10 mg/day, which was increased to 20 mg/day by day 7. On day 8 he complained of "something wrong with his mouth," later saying that it was his throat. His pulse was 92 and his respiratory rate 16. One hour later he was found gasping in his bed, complaining that he could not breathe. He was extremely anxious and had intraclavicular retraction and stridor. Throat exam was normal; the epiglottis was visualized, but no abnormalities were noted. There was some tightness in the posterior neck muscles, which the patient later reported as painful. Mr. B was given 50 mg of diphenhydramine I.V., which produced a rapid improvement in breathing, muscle tension, and anxiety.

He was placed on oral benztropine, 2 mg b.i.d., without subsequent extrapyramidal symptoms or breathing difficulties. Two weeks later the benztropine was discontinued without any subsequent reactions.

Discussion

Most cases of sudden death associated with phenothiazines have been with the more sedating drugs (2). Many cardiac abnormalities have been reported with phenothiazine death (2, 3). Grollman (4) has noted that chlorpromazine acts directly on the autonomic centers of the midbrain and produces a blocking effect on sympathetic ganglia, resulting in hypotension. Postural hypotension is another possible cause of death, particularly in elderly patients given chlorpromazine. Unfortunately, as Leestma and Koenig (2) have noted, autopsy findings are not conclusive. As Peele and Von Loetze (5) suggested, it should also be remembered that there were sudden deaths in patients with lethal catatonia before the advent of phenothiazines.

There have been reports of syndromes similar to those we have described. Malitz and associates (6) and Solomon (7) have observed a similarity in symptoms between phenothiazine-associated sudden death and a bulbar palsylike syndrome. Plachta (8) has speculated that asphyxia might be caused by a disorder of the cricopharyngeal sphincters. Haeffner and associates (9) reported pharyngeal muscle spasm, neck cramps, swelling of the tongue, and cyanosis associated with phenothiazine treatment.

Our cases are similar to these in that the patients did not die. One patient was clearly cyanotic, and if he had not received diphenhydramine his course could have been different. Haeffner and associates (9) noted that pharyngeal spasms are usually relieved by antiparkinsonian drugs. Victor and Adams (10, p. 831) noted the efficacy of diphenhydramine in treating true parkinsonism, especially when used in combination with anticholinergics. The theoretical basis for this use is not certain. We chose diphenhydramine because it is easier to titrate and we have found its subjective antianxiety effect to be greater. We have encountered several other patients who experienced dyspnea and diffi-

When this paper was written, Dr. Flaherty was Chief, Psychiatry Service, and Dr. Lahmeyer was Chief, Inpatient Psychiatry, Veterans Administration Westside Hospital, Chicago, Ill. Both authors are now Assistant Professors, Department of Psychiatry, Abraham Lincoln School of Medicine, University of Illinois, 912 South Wood St., Chicago, Ill. 60680.

cult breathing within 1–2 weeks of starting haloperidol. The drug relationship was less clear because of previous drug use in one patient, the combination of haloperidol with lithium in another, and milder symptoms in a third. However, all reported subjective improvement following diphenhydramine treatment.

Is it possible that these patients were suffering from a laryngeal dystonia? Laryngeal spasms after intubation are known to compromise breathing. Also, dystonias are common in young men taking haloperidol during the first few days of treatment. These two patients experienced the symptoms early in the morning when blood levels are falling. This temporal relationship has been noted with dystonias. Both patients responded to diphenhydramine and had no recurrence on maintenance benztropine. The nonspecific sedative effects of intravenous or intramuscular anticholinergics might also account for the diminution of the subjective distress. As is the case with dyspnea in general, our patients seemed to be in marked subjective distress. The objective signs in these cases seem to rule out the possibility of simple panic attacks with hyperventilation, although a component of this seems likely. Allergic reactions seem unlikely because there were no other signs of allergic response, such as rash or wheezing.

The association between this syndrome [illegible] es of phenothiazine deaths is uncertain. [illegible] is a potentially lethal syndrome that respo[illegible] ment. Confirmation of our findings require[illegible] servations.

Increase in Serum Prolactin by Exogenous and Endogenous Opiates: Evidence for Antidopamine and Antipsychotic Effects

BY MARK S. GOLD, M.D., D. EUGENE REDMOND, JR., M.D., RICHARD K. DONABEDIAN, M.D., FREDERICK K. GOODWIN, M.D., AND IRL EXTEIN, M.D.

There is extensive evidence from in vitro and in vivo studies of man and other primates (1) that prolactin secretion is predominantly controlled by a tonic inhibitory dopaminergic mechanism. The involvement of dopamine in the tonic inhibition of prolactin secretion and the action of antipsychotic medications at dopamine receptors have led to the suggestion that antipsychotic drugs can be identified by their stimulation of prolactin secretion (2, 3). Potent antipsychotic medications block dopamine receptors (3, 4) and stimulate prolactin secretion (2, 3); structurally similar drugs without such effects do not. These and more recent data suggesting that the prolactin-stimulation model predicts antipsychotic efficacy and cli[illegible] of me have led to the hypothesis that tube[illegible] dopamine blockade can be assessed in [illegible] tions in serum prolactin and that this [illegible] might be the best model system for scree[illegible] psychotic compounds (2, 3).

Dr. Gold is Vice President for Basic Research, Psychiatric Institutes of America, and Director of Research and Training, Fair Oaks Hospital, 19 Prospect St., Summit, N.J. 07901. Dr. Redmond is Associate Professor of Psychiatry, Yale University School of Medicine, New Haven, Conn., where Dr. Donabedian is Professor of Laboratory Medicine. Dr. Goodwin is Chief, Clinical Psychobiology Branch, National Institute of Mental Health, Bethesda, Md., where Dr. Extein is Mental Clinical Associate.

Method

We studied the effect of morphine and [illegible]-8[illegible] (5), a synthetic *d*-alanine methionine-enk[illegible] ative, on serum prolactin in primates [illegible] month of acclimatization to the sample c[illegible] cedure (6), four *Macaca arctoides* wer[illegible] venous infusions of morphine sulfate and [illegible] two dosage levels, 0.4 mg/kg and 0.04 mg[illegible] dol, 0.1 mg/kg; and saline solution. As [illegible] viously (6) all monkeys received one of [illegible] dosage levels every week. Each experim[illegible] lasted 5 hours. During the last 4 hours [illegible] were drawn and drugs were administe[illegible] venous cannula, without handling or [illegible]

0002-953X/78/0011-1415$0.35 © 1978 American Psychiatric Association

Samples were taken at 60, 30, and 15 minutes before drug infusion, at the time of infusion, and at 15, 30, 45, 60, 90, 120, 150, and 180 minutes postinfusion. All samples were placed on ice and centrifuged within 1 hour. Serum was frozen at −20°C until assay. Prolactin was measured in duplicate by radioimmunoassay (6).

Results

Morphine in the 0.4 mg/kg dose produced a significant ($p<.01$) elevation in basal serum prolactin (expressed as nanograms per milliliter) from a mean (±SEM) of 16±2.75 to 64.25±13.3. Serum prolactin was significantly elevated at all time points from 15 to 90 minutes postinfusion. No significant increase in prolactin was found with the 0.04 mg/kg dose. FK 33-824 at both dosage levels produced a significant and sustained elevation in serum prolactin. Prolactin was significantly elevated ($p<.01$) from baseline at all time points after administration of 0.4 mg/kg of intravenous FK 33-824. Peak levels at 45 minutes postinfusion were 177.0±22.9.

The 0.04 mg/kg dose of FK 33-824 produced significant increases ($p<.01$) in serum prolactin at time points from 15 to 60 minutes after infusion. The peak level at 45 minutes postinfusion was 95±9.6. Haloperidol (0.1 mg/kg) produced a significant increase in serum prolactin to peak levels of 115.3±9.6. Saline did not produce any significant effects on serum prolactin.

Discussion

These data support speculations, behavioral studies, anecdotal reports from the era before antipsychotic medication, clinical experience in methadone maintenance programs, and recent pilot studies with psychotic humans that opiate agonists may be antipsychotic in man (7, 8).

Support for this hypothesis comes from data which suggest that, like the traditional antipsychotic medications, morphine, methadone, and other opioid agonists interfere with the postsynaptic action of dopamine (7, 9). Opiate agonists increase dopamine metabolites homovanillic acid and dihydroxyphenylacetic acid in rat brain and inhibit the enzyme dopamine-stimulated adenylate cyclase (9), as does the meperidine derivative haloperidol. These actions of opiate agonists are consistent with the prediction of antipsychotic efficacy on the basis of current theories of psychosis and the antipsychotic locus of action of the neuroleptics (4). Additional support for the prediction of antipsychotic efficacy comes from recent studies demonstrating that morphine and methadone increase serum prolactin in man and nonhuman primates (7) and endogenous opioid peptides increase serum prolactin in rodents by stimulation of opiate receptor sites that inhibit dopamine release (10). These prolactin data are consistent with the dopamine metabolite data which suggest that opiate agonists stimulate opiate receptors in brain to modify dopamine impulse flow and release, thereby interfering with the postsynaptic action of dopamine. Endogenous opioid peptides, the endorphins, may act as an inhibitory neuromodulator of dopamine activity, so that an endorphin deficiency could result in increased dopamine release and turnover and possibly psychosis. Clinical trials of endorphins, including the synthetic pentapeptide enkephalin FK 33-824, could provide extremely valuable tests of the current hypotheses of psychosis and conceivably could give clinicians an antipsychotic medication that, as a derivative of an endogenous compound, might reverse a primary deficiency state.

If opiate agonists are not antipsychotic in man, then a number of widely used model systems, (including serum prolactin, catalepsy reversed by apomorphine, dose-related elevation in dopamine metabolites, and inhibition of dopamine-stimulated adenylate cyclase) may not be particularly relevant to the antipsychotic locus of action of the neuroleptics.

Another Look at Gluten in Schizophrenia

BY JAMES R. RICE, M.D., CHARLES H. HAM, M.D., AND WILLIAM E. GORE, PH.D.

Singh and Kay recently reported that

> schizophrenics maintained on cereal free diet and milk free diet and receiving optimal treatment with neuroleptic showed an interruption or reversal of their therapeutic progress during a period of blind, wheat gluten challenge. The exacerbation of the disease process was not due to variations in neuroleptics. After termination of the gluten challenge, the course of their improvement was reinstated. The observed effects seemed to be due to a primary schizophrenia-promoting effect of wheat gluten. (1, p. 401)

According to Dohan and Grasberger,

> Routinely treated schizophrenics, who on admission were randomly assigned to a diet free of cereal grains and milk while on a locked ward, were discharged from the hospital about twice as rapidly as control patients assigned to a high-cereal diet. Wheat gluten secretly added to the cereal-free diet abolished this effect. These and previous findings suggest that cereal grains may be pathogenic for those hereditarily predisposed to schizophrenia just as they are for celiac disease, a disorder that may be genetically related. (2, p. 685)

In previous writings Dohan (3) suggested that there is a genetic relationship between celiac disease and schizophrenia; he also suggested that there may be some correlation between the decreased incidence of schizophrenia and the decreased consumption of gluten products during World War II in Germany.

We decided to test the hypotheses that 1) chronic schizophrenics would experience an exacerbation of their illness after an increase in gluten intake, and 2) chronic schizophrenics who were receiving optimum treatment with neuroleptics would improve further with a diet lower in gluten.

Method

We began the study with 21 patients diagnosed as schizophrenic (5 schizo-affective, 11 paranoid, and 5 chronic, undifferentiated type). Five patients dropped out: 2 who left the hospital without permission, 1 who became too agitated to participate, 1 who was diagnosed as having lupus erythematosus, and 1 whose functioning was inadequate for continued participation. The 16 patients who completed the study had a mean of 9 years of hospitalization and a mean age of 38. Patients were selected according to Carpenter and associates' 12-point diagnostic system (4), a record review, and a history of chronic schizo[illegible] spent the first 6 weeks assessing base[illegible] functioning and adjusting neuroleptics t[illegible] mum level of functioning. During this [illegible] tient was rated twice on the Brief Psy[illegible] Scale by a blind rater. During the 6-wee[illegible] od patients were on a regular institu[illegible] ceived 30 g of soy flour blended in wit[illegible] sugar. Then an excess of gluten was [illegible] their regular diet by substitution of glute[illegible] in weekly intervals, starting with 30 g [illegible] by 5 g/week to a maximum of 45 g. At [illegible] week of increased gluten, patients we[illegible] blind rater using the Brief Psychiatric [illegible] and clinical observations were made by [illegible] nel using the Missouri Mental State[illegible] Scale. After the gluten phase we retur[illegible] Kool Aid drink phase for 4 weeks to [illegible] blind rating of the patient's level of fun[illegible] patient then began a gluten-free and mi[illegible] weeks, during the first 4 weeks of whic[illegible] soy drink. (All patients gave informed [illegible]

Results

After the gluten phase, 1 patient of [illegible] severe regression below baseline on t[illegible] atric Rating Scale and clinical obser[illegible] had paranoid schizophrenia since she [illegible] and has been in the South Carolina S[illegible] 14 years. She is now 29 years old. W[illegible] gesting excess gluten, she became se[illegible] uncooperative, and paranoid. We had [illegible] the gluten drink and give her intramus[illegible] for three days because she became u[illegible] refused to take her oral medications. of her improvement we were able to discharge her from the hospital and send her home to her family.

Discussion

In human research many variables can affect human behavior and the results of that research. We might conclude that the largest percentage of schizophrenic patients are not affected by gluten in their diet, but a small percentage of patients may be affected. According to Pfeiffer, "Dohan finds that 4 percent of hospitalized schizophrenics are sensitive to wheat gluten" (5, p. 417). Our work did not duplicate the success that was reported previously (1, 2). Since we studied only a few patients, we feel that additional studies involving more patients are necessary to confirm our conclusions.

Reaction to Relaxation and Desensitization Outcome: Five Angry Treatment Failures

BY STEPHEN I. ABRAMOWITZ, PH.D., AND NOA WIESELBERG

The role of relaxation, once regarded as critical to successful desensitization, has come under increasing scrutiny in recent years. In Wolpe's original formulation (1), systematic desensitization was conceived as a counterconditioning process that required the pairing of the anxiety-evoking stimulus with an antagonistic response—usually muscle relaxation. However, London (2) suggested that the extinction procedure alone accounts for the major effects of desensitization. More recently, Rachman (3) and others have turned attention to such cognitive mediators as mental calmness, relabeling, and expectations. Empirical efforts directed toward extricating the comparative contributions of various aspects of relaxation to effective desensitization have yielded inconclusive findings (4). Some data support the counterconditioning position, whereas others dictate modification of the premise that certain components of relaxation training are essential ingredients.

Almost all of the relevant studies have been predicated on the assumption that technique variables alone explain desensitization outcome. However, it seems reasonable to suggest that the patient's ability or willingness to relax mediates any facilitative effect of relaxation training, physiological or otherwise. The inclusion of subjects who are relatively unreceptive, as well as those more receptive to relaxation, in desensitization-with-relaxation groups may attenuate the apparent impact of the training procedure.

This report is based on a project designed to illuminate the role of individual differences in imaging vividness in mediating the relative effectiveness of symbolic and in vivo desensitization of snake phobia.[1] Our data are entirely serendipitous: they were discovered on reviewing responses to a treatment evaluation item that asked if subjects had become angry when told to relax. However, they offer a fresh look at the old question of the place of relaxation in formulations of desensitization.

Method

Sixty-three persons who responded to newspaper announcements of the availability of treatment for snake phobia were administered the Fear Survey Schedule (5), an adaptation of the Attitudes Toward Snakes Scale (6), and the Behavioral Avoidance Test (7). Those 48 individuals who proved to be behaviorally phobic on the latter were randomly assigned to either imaginal or in vivo desensitization. From subgroups of 36 subjects who subsequently met a behavioral criterion of treatment success and 12 who did not, we obtained follow-up samples of 17 and 5, respectively. Nine original subjects treated by one of us (N.W.) were eliminated from the follow-up to reduce the potential for experimenter bias. Of the 17 remaining subjects who did not participate, roughly equivalent num-

Dr. Abramowitz is Associate Professor of Psychology in Residence, Department of Psychiatry, University of California, Davis, School of Medicine, 2315 Stockton Blvd., Sacramento, Calif. 95817, where Ms. Wieselberg is a doctoral candidate in clinical psychology.

The authors wish to acknowledge the contributions of John M. Dyckman.

[1]The follow-up data are based on N.W.'s senior thesis, which was an outgrowth of a dissertation done by John M. Dyckman under the supervision of Philip A. Cowan at the University of California, Berkeley, submitted for publication as "Imaging Vividness and the Outcome of in vivo and Imagined Scene Presentation."

 0002-953X/78/0011-1418$0.35 © 1978 American Psychiatric Association

bers had left the area, could not be reached by phone, or repeatedly failed to keep follow-up appointments.

Six advanced undergraduates trained in desensitization theory and technique conducted the five-session standardized treatments. Each session lasted about half an hour, and the five sessions were spaced over a 2½–3-week period. Both forms of desensitization were conducted in the same room. Fuller descriptions of the assessment battery and treatment procedures can be obtained from N.W.

The same two instruments and behavioral test taken previously were completed at posttesting. For the purpose of this research, whether or not a subject was able to handle the snake at that time was the behavioral criterion for assignment to the successfully or the unsuccessfully desensitized subgroup.

Subjects were invited to the clinic for follow-up approximately 9 months after treatment. They once again completed the psychometric measures and behavioral test and filled out brief treatment generalizability and satisfaction scales. The latter device included the statement: "I was angered when I was told to relax." Subjects were classified by their retrospective agreement or disagreement with this item.

Results and Discussion

All 5 individuals who did not meet the posttreatment behavioral criterion but only 1 of the 17 who did recalled having reacted angrily to being told to relax, a statistically significant difference ($p<.001$, Fisher's exact test, two-tailed).

To rule out the likelihood that initial differences in anxiety might have influenced reactions to the instruction to relax and thus the relationship with desensitization outcome, successful subjects' pretreatment means were compared with unsuccessful subjects' means on the psychometric and behavioral measures. No significant differences were found. However, the unsuccessful subjects' recollections of annoyance at receiving relaxation instructions could have resulted from a process of defensive rationalization. In that case, the negative reactions would have been a by-product of, rather than a factor in, the treatment failure.

O'Donnell and Worell (8) found that [illegible] rated depth of relaxation was related to [illegible] desensitization of anger. The present data [illegible] extend to a circumscribed phobia the notion that individual differences in perceived responsiveness to [illegible] cular relaxation are correlated with [illegible] outcome. Consistent with Borkovec and [illegible] servations (4), replication attempts [illegible] more seriously phobic individuals and [illegible] nonspecific demands for improvement.

The results support Rachman's emphasis [illegible] calmness (3), as well as the venerable [illegible] putatious (9) view of relaxation as an [illegible] gredient in successful desensitization. Clients may be less willing than others to relax when placed in an anxiety-arousing situation or, conceivably, such individuals are prone to relaxation resistance when asked to relax. Such information could lead to more efficient desensitization and the development of pretesting procedures to identify patients who are likely to encounter difficulty.

Treatment of Imipramine-Resistant Depression and Lithium-Refractory Mania Through Drug Interactions

BY BARNETT MEYERS, M.D.

Discoveries in the area of drug interactions are of potentially great import to the practice of clinical psychiatry. Recent reports in the literature have demonstrated the usefulness of supplementing supposedly therapeutic dosages of imipramine with methylphenidate to raise blood levels of the antidepressant in previously unresponsive patients (1) and of adding chlorothiazide diuretics to lithium to reverse a nephrogenic diabetes insipidus (NDI) syndrome and to achieve satisfactory serum lithium levels (2).

The following case report involves the application of both techniques in a patient who had been resistant to treatment.

Case Report

The patient, a 33-year-old divorced man, was transferred to Northern Westchester Hospital after 2 weeks of treatment at a county facility for an acute manic episode. The patient had been hospitalized three times in the past 5 years because of affective illness and had a history of recurrent alcohol abuse, which increased during each manic episode including the present one. He had been treated on an outpatient basis for more than 1 year with 1800 mg of lithium carbonate and 100 mg of chlorpromazine a day. On admission to the county hospital, his serum lithium level was 0.9 mEq/liter. The daily dosages were then increased to 2100 mg of lithium and 200 mg of chlorpromazine, but the serum lithium level fell during the next 2 weeks to 0.67 mEq/liter.

When the patient was transferred to Northern Westchester Hospital, he was agitated, with a labile, expansive, and predominantly angry affect. He demonstrated flight of ideas and reported thought racing and insomnia. He had persistent paranoid ideation but no delusions or hallucinations. The sensorium was clear.

At Northern Westchester Hospital, the patient was continued on 2100 mg of lithium carbonate and 200 mg of chlorpromazine a day. The urine specific gravity (SG) on admission was 1.005. Other laboratory studies, including serum electrolytes, were normal. He complained of severe polyuria and polydipsia. A repeat morning urine SG of 1.005 was obtained, and the 24-hour urine volume was found to be 6800 cc. Renal concentrating ability in response to dehydration or vasopressin was not tested. Because of the gross evidence of lithium-induced NDI, the patient's lithium dosage was reduced to 1200 mg/day, and 50 mg/day of hydrochlorothiazide was added. One week later, the urine volume had fallen to 4900 cc, with the serum lithium level remaining constant at 0.65–0.70 mEq/liter. Further adjustments of both the diuretic and lithium were made, and at daily dosages of 1200 mg of lithium and 100 mg of hydrochlorothiazide, the patient's daily urine output fell to 2200 cc, with a morning SG of 1.014. The serum lithium rose to 0.93 mEq/liter and the manic affect disappeared. This was followed by the onset of depression. The chlorpromazine was discontinued, lithium was continued, and imipramine was started. The patient manifested depressed affect, hypersomnia, and lassitude and expressed feelings of hopelessness and helplessness. The depression persisted unchanged after 4 weeks of treatment with 250 mg/day of imipramine. Methylphenidate, 10 mg/day, was started, and within 1 week the patient's mood improved. He was discharged in complete remission. Two weeks later the methylphenidate was discontinued without any return of depression. The imipramine dosage was tapered off and eventually discontinued, and the patient has been maintained for 1 year on daily doses of 1200 mg of lithium carbonate and 50 mg of hydrochlorothiazide, with potassium supplements. His affect has remained stable and normal, he has returned to work, and he has not resumed drinking.

Discussion

The treatment decisions in this case relied heavily on clinical investigations of imipramine and lithium interactions with other medications. Glassman and Perel (3) have reviewed the literature demonstrating wide individual variations in the metabolism of tricyclic antidepressants and of blood levels after a given oral dose. Glassman and coworkers (4) recently added to the body of knowledge indicating that blood levels are closely correlated with clinical response by suggesting that there seems to be a therapeutic threshold serum level for imipramine. Levels achieved are largely determined by the hepatic microsomal enzyme system, which is known to be influenced by a variety of pharmacologic agents. Barbiturates, alcohol, and nicotine, putative enzyme inducers (5), would thus be expected to reduce the blood levels and clinical efficacy of imipramine. This patient's episodes of binge drinking before admission might have contributed to his unresponsiveness to the 250-mg dosage of imipramine (3.8 mg/kg).

Wharton and coworkers (1) used methylphenidate's property as a microsomal enzyme inhibitor to cause a 250% increase in plasma imipramine and successfully treated a series of patients who had unipolar depression that was previously unresponsive to treatment. The patient discussed here differed from their sample in that he had bipolar illness. It is of note that the addi-

tion of methylphenidate did not "switch" this patient into a manic or hypomanic illness, possibly because of a prophylactic effect of his maintenance lithium level.

The major clinical problem encountered in this case was the treatment of a manic episode in a bipolar patient who developed signs of lithium-induced NDI. This syndrome is thought to result in part from the inhibition by lithium of the action of vasopressin on renal adenyl cyclase, resulting in diminished distal reabsorption of water (6, 7). Although a definitive work-up for this syndrome was not done, presumptive evidence for its presence was found in the excretion of nearly 7 liters of urine per day, with polydipsia and low specific gravity morning urines. The reversal of all of these abnormalities on a reduced dosage of lithium in combination with hydrochlorothiazide supports this diagnostic impression. Himmelhoch and associates (2) demonstrated that "thiazide-lithium synergy" can reverse the NDI syndrome and produce clinical improvement in lithium-refractory patients. This effect is presumed to result from a relatively greater reabsorption of lithium along with sodium in the proximal tubule secondary to relative sodium depletion (2). Consequently, serum lithium would increase, while less lithium would reach the distal tubule and collecting system to interfere with vasopressin activity. It could be speculated further that the consequent reduction in lithium dosage further diminishes the absolute amount of lithium reaching and affecting the distal kidney. This mechanism is more complex than that posited to explain the action of hydrochlorothiazide in reversing non-lithium-induced NDI (8).

Conclusions

It has been estimated that approximately 70% of significant depressive episodes respond to supposedly adequate oral dosage of imipramine (9) and that 80% of manic episodes respond to lithium (10).

Idiosyncratic rapid metabolism of the tricyclic has been offered as an explanation for some imipramine treatment failures (3) while the developme[illegible] syndrome may explain many lithium failu[illegible] I have described is an additional demon[illegible] applying principles of drug interaction ca[illegible] numbers of patients who are fundamental[illegible] sive to these two therapeutic agents. The [illegible] ticularly noteworthy in that the admini[illegible] methylphenidate to a patient with bipol[illegible] maintenance serum lithium levels did n[illegible] recurrence of a manic episode.

Phenelzine-Induced Psychosis

BY L. MICHAEL SHEEHY, M.D., AND JERROLD S. MAXMEN, M.D.

There is a growing body of evidence suggesting that monoamine oxidase inhibitors (MAOIs) exert therapeutic effects on patients who have a heterogeneous group of "neurotic" depressive disorders, some of which have been labeled "atypical depression" (1), "hysteroid dysphoria" (2), and "phobic anxiety-depersonalization syndrome" (3). Although symptom patterns vary, patients with these disorders often have persistent dysphoria, hysterical traits (e.g., rejection sensitivity, overreactive affect), phobias, panic attacks, chronic anxiety, hypersomnolence, lethargy, hyperphagia, inverse diurnal mood variation, and initial insomnia. Classical vegetative signs of depression and psychotic symptoms are absent.[1] Because these individuals constitute a large proportion of outpatients and because the wider use of MAOIs for these patients is rapidly gaining acceptance in North America (4), it is becoming increasingly important to be aware of their desirable and undesirable effects.

Some authorities maintain that the overall incidence of MAOI side effects, with the possible exception of hypertensive crisis, has been underestimated (2), especially behavioral toxicities (4). In this paper we will describe a patient who seemed to have had a phenelzine-induced psychosis that did not resemble the usual, albeit infrequently reported, behavioral side effects of MAOIs.

Case Report

The patient was a 30-year-old married part-time student who complained of depression, academic difficulty, shyness, fears that she was not heterosexual (despite absence of homosexual feelings), little enjoyment from life, and failure to achieve orgasm during sexual intercourse. The patient had experienced these symptoms for 9 years, with the exception of shyness, which had existed since childhood. Anorexia, weight changes, delusions, hallucinations, hypomanic or psychotic symptoms, and suicidal ideas were absent. The patient's history did not reveal other psychiatric symptoms or substance abuse. Family history included chronic depression in her mother, father, and sister, without history of psychiatric hospitalization. The patient was given a diagnosis of chronic depressive disorder.

Because of the absence of endogenous features and the presence of initial insomnia and a tendency to oversleep, the patient was started on phenelzine, 45 mg/day p.o. Thirteen days after medication was begun, she experienced 2 days of slight drowsiness, which cleared spontaneously. Eight days later, she suddenly became terrified that she and her husband would kill each other. She experienced a friend's voice on the telephone as deep and sinister and noted that her husband's eyes also looked evil. She ran from the house in terror after becoming convinced that a cockroach she had seen was growing larger and would shortly explode. In addition, she expressed the conviction that she had been sexually abused by a male friend of her husband's, with the husband's compliance. Reassurance that this had not occurred did not prove helpful. Phenelzine was discontinued and the patient was given oral flurazepam, 30 mg, and haloperidol, 5 mg, by a physician friend. Despite this medication, she remained afraid of killing her husband, thought she might jump out a window, and was still actively delusional when she was admitted to the hospital 18 hours after the symptoms began.

Mental status on admission. The patient was a slender, shy, attractive woman with a gentle manner. Her affect was labile, shifting from anxiety to depression, and her mood was depressed. She was distractible and circumstantial and recalled many events from her childhood. Formal tests of attention, as well as memory functions and orientation, were completely normal. The primary admission diagnosis was atypical psychosis. Brief reactive psychosis and drug-induced delusional disorder were considered as alternate diagnoses.

Hospital course. The admission physical examination, review of nonpsychiatric systems, and vital signs were within normal limits. The patient was treated solely with psychosocial care, apart from one 10-mg dose of oral diazepam for restlessness. The first night in the hospital was characterized by periodic awakening in great fear. Within 24 hours all symptoms disappeared spontaneously and the patient appeared tired and more depressed than she had been before the symptoms appeared. She said she missed the intense moments of feeling she had experienced during her illness. Her symptoms remained absent after 48 hours of hospitalization and she was discharged with a diagnosis of drug-induced delusional disorder (*DSM-III*). She has been followed for 4 months since her discharge, and there has been no recurrence of her symptoms. A trial of imipramine, 200 mg/day for 1 month, produced no therapeutic benefits or side effects other than dry mouth.

Discussion

After 21 days of a regimen consisting of 45 mg/day of phenelzine this chronically depressed woman abruptly developed intense fears of losing control (e.g., becoming assaultive and suicidal), paranoid ideation, quasi-delusional perceptions, labile affect, distractible speech and thought, hypermnesia for childhood events, paninsomnia, thematic circumstantiality, and heightened emotional intensity. She had no signs of an organic brain syndrome or of a hypertensive crisis. There was no evidence of precipitating environmental stress. Her psychosis resolved within 48 hours after phenelzine was discontinued.

The authors are with the Columbia University College of Physicians and Surgeons, where Dr. Sheehy is Assistant Professor of Clinical Psychiatry and Vice Chairman, Department of Psychiatry, and Dr. Maxmen is Associate Professor of Clinical Psychiatry and Director of Undergraduate Training in Psychiatry. The authors are also with the New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032, where Dr. Sheehy is Deputy Director and Dr. Maxmen is Psychiatrist III.

[1]Unpublished data from F. Quitkin, A. Rifkin, and D. F. Klein.

0002-953X/78/0011-1422$0.35 © 1978 American Psychiatric Association

Although the cause of her brief psychosis cannot be determined with certainty, it appeared to be either a direct phenelzine-induced side effect or a drug-triggered psychosis in a highly vulnerable patient. Because the psychosis occurred when full clinical response to phenelzine would first be expected and resolved promptly after it was discontinued, it appears that phenelzine was the offending agent. Although readministering the drug would have helped to determine if the patient had a phenelzine-induced psychosis, this action was precluded by ethical considerations.

An alternative hypothesis is that the patient's psychosis was completely unrelated to phenelzine. This explanation is implausible because of the absence of a precipitating environmental stress, the timing of the onset, and the prompt resolution after phenelzine was discontinued.

An unusual aspect of this apparent phenelzine-induced psychosis is that it did not resemble the types of behavioral toxicities previously attributed to MAOIs. The overall incidence of these toxicities averages between 11% and 15%. The most frequently observed behavioral side effects have been hypomanic and manic episodes, restlessness, hyperactivity, agitation, irritability, and occasional confusion (4).

Treatment of Leukopenia with Lithium Carbonate: A Preliminary Report

BY RAMZY YASSA, M.D., VASAVAN NAIR, M.D., AND GEORGE SCHWARTZ, B.SC.

Although lithium treatment is not usually associated with blood dyscrasias, hematologic changes associated with the drug have been reported in both men and animals. These changes are in the direction of leukocytosis. Mayfield and Brown (1) observed white blood cell (WBC) counts as high as 16,000 cells/mm^3 in a group of 11 male manic patients treated with lithium carbonate. They reported a consistent WBC elevation in all patients. Murphy and associates (2) reported a similar WBC increase in 20 depressed and 11 manic patients during administration of lithium carbonte. O'Connell (3) reported an intermittent leukocytosis in 25 psychiatric patients maintained on lithium carbonate. Shopsin and associates (4) examined peripheral blood specimens from 22 hospitalized psychiatric patients: 21 patients showed leukocytosis during lithium treatment that was not related to diagnosis, severity, or duration of illness. These findings prompted us to administer lithium carbonate to thre
consistently showed leukopenia.

*Significantly different from prelithium baseline ($p<.05$, t test).

during the 6-week trial or the preceding 3-month period.

Results

There was a consistent and significant increase in total WBC as well as in the neutrophil count in these patients during the 3 weeks of lithium administration, reaching a maximum by the end of the third week (see table 1). After discontinuation of lithium, there was a steady decline to baseline levels. The WBC increase was not correlated with serum lithium levels.

Discussion

Our results indicate that lithium carbonate counteracted leukopenias induced by phenothiazines in 2 patients and by barbiturates in 1. Greco and associates (5) and Stein and associates (6) have also found that lithium corrects neutropenia caused by cancer chemotherapy. Gupta and associates (7) have been successful in treating neutropenia accompanying Felty's syndrome with lithium.

The mechanism of lithium's hematologic action has not been established. Lithium ions stimulate granulopoiesis in vivo (2, 8) and in vitro (9). Lithium has been reported to act by increasing production rather than by redistributing granulocytes from the bone marrow to the circulating granulocyte pool (8, 10). This finding may be of great importance in the treatment of leukopenia due to various causes.

Criticisms of published articles will automatically be sent to th[illegible] response. Letters will be edited for clarity and conformance with* Journal *style. We regret that we [illegible] writers of the disposition of letters or return those which are not printed.*

Megavitamin Therapy for Autistic Children

SIR: We wish to respond to the brief report entitled "The Effect of High Doses of Vitamin B_6 on Autistic Children: A Double-Blind Crossover Study" (April 1978 issue) by Enoch Callaway, M.D., Bernard Rimland, Ph.D., and Pierre Dreyfus, M.D. Unfortunately, a number of serious methodological flaws in the study make its conclusions misleading in several respects.

Two flaws pertain to the sample. There is considerable question regarding diagnostic accuracy for the children studied. In the report's title, the sample is termed "autistic," while in the body it is alternately referred to as "autistic" or "autistic-type." This discrepancy is quite confusing, especially in view of the fact that the senior investigator asserted elsewhere (1) the importance of precise diagnosis in relation to such severely disturbed children. He himself has advocated diagnostic distinction between "autistic" and "autistic-type" children, lamenting the blurring of the criteria that had confounded previous double-blind studies (2); using the senior author's own diagnostic criteria, less than half of the sample qualified as classically autistic. Brief mention of this limitation in the Comment section of the report does not negate the grave constraint imposed on external validity.

Even more serious limitations result from the sampling recruitment procedures. All children who participated in this study had formerly been identified as vitamin-sensitive. At best, then, the findings pertain only to that sector of the population of autistic-type children who are vitamin-sensitive. Any generalization from such findings to autistic children as a group is premature and unwarranted.

The study's third major area of difficulty involves behavior rating procedures. The reader is not given information regarding the actual criteria by which the behavioral data were rated, nor are interjudge reliability data provided. Without such information, the reader has no assurance that different judges would have made inferences similar to those reported and is unable to replicate the study.

The authors correctly predicted behavior patterns for 11 out of 15 children. Thus, almost one-third of the cases were misclassified. Moreover, the authors claim accurate prediction regardless of the magnitude of their success—some of the classifications depended on mere one-point judgment differences. In addition, prediction was accurate for only 4 of the 6 reliably autistic children, not a significant proportion.

Other design shortcomings include lack of direct control over experimental implementation by parents and failure to specify other medications being taken concurrently by subjects, thus ignoring possibly crucial chemical [illegible] fects.

In conclusion, because of serious flaws in [illegible] racy, sampling recruitment, and reliability of [illegible] the new study, inferences regarding the ef[illegible] doses of vitamin B_6 with autistic children sho[illegible] as very tentative and subjected to rigorous [illegible] tiny.

The seriousness of the disorder for the fa[illegible] and the desperation with which parents awai[illegible] tory explanations and improved treatment f[illegible] they face demand that more than the usual [illegible] cautions be applied to work in this area. To [illegible] conclusions is a grossly unfair enticement to [illegible] in distress.

HAROLD BOV[illegible]
Succe[illegible]

Dr. Callaway and Associates Reply

SIR: Ms. Moss and Dr. Boverman co[illegible] some of the points we made in our article. [illegible] clinically heterogeneous, and the nature of [illegible] lation precluded the use of many otherw[illegible] trols and refinements. They might also hav[illegible] remark that none of the children had bee[illegible] megavitamin regimes. We are delighted tha[illegible] ther investigation is called for.

They do fall into the common error of [illegible] measure of reliability is needed before positi[illegible] accepted. Low reliability could indeed giv[illegible] when a real effect existed (false negative), b[illegible] chance effect, then the level of reliability [illegible] used is a moot point. (Had it been possible, w[illegible] included a measure of reliability.)

The invidious implications of their last paragraph seem uncalled for. The therapy, B_6, and even Rimland's more extensive regimen, is safe. At worst, they cause upset stomachs. On the other hand, some percentage of autistic-type children seem to be helped by B_6, and this impression is supported by double-blind withdrawal. These are observations, not conclusions.

We regret that our efforts upset Ms. Moss and Dr. Boverman to the point where our observations become "conclusions" and "grossly unfair enticement" to the parents of their patients. We can only hope they will join us in our active commitment to the "rigorous empirical scrutiny" which they recommend to others.

Sex Role Identification

SIR: The article by David Krueger, M.D., "Symptom Passing in a Transvestite Father and Three Sons" (June 1978 issue) raises an important theoretical point about the roles of observation, identification, and modeling in inappropriate sex-role behavior. We recently evaluated a 21-year-old patient in our clinic who reported concerns about cross-dressing behavior of ten years' duration. An interview with the patient's mother indicated that our patient's father was a "private transvestite" in that he wore a woman's nightgown in their bedroom. However, she reported that the patient had never directly observed this behavior. The patient did acknowledge hearing many fights between his parents, but never reported any awareness of his father's cross-dressing. Unfortunately, our patient has failed to return to the clinic for further evaluation, leaving us with an incomplete understanding of the paternal parent's contribution to our patient's transvestism. Nonetheless, we agree with Dr. Krueger that the role of the father should be examined in great detail in future studies of transvestism.

DUANGJAI KASANTIKUL, M.D.
HOWARD ROBACK, PH.D.
Nashville, Tenn.

Dr. Krueger Replies

SIR: Drs. Kasantikul and Roback point out one of several questions and areas of potential exploration regarding the roles of modeling, observation, and imitation in the identification process, especially as these processes relate to sexual role identity vis-à-vis the (inadequately studied) role of fathers. The absence of fathers has been demonstrated to be a psychopathological force to young children. Factors that have hindered consideration of the importance of fathers in development—besides their either providing a supportive environment or being absent—may include physical inaccessibility of fathers due to work, the provision of basic nourishment and affection by the mothers in the child's early years, resistance of the fathers to becoming therapeutically involved, and, perhaps, the immunity of patriarchy. These factors may have contributed to the fact that the literature deals mostly with the extreme situation of the absence of the father and does not deal sufficiently with less extreme situations.

The question implied by Drs. Kasantikul and Roback is the *necessity* for observation per se to occur in determining the specificity of a symptom choice in sexual role identity conflicts. Although not answered completely, there are suggestions in the literature which may serve to shape further research in this area.

The attitudes and examples communicated from parent to child are powerful and instrumental in creating masculine and feminine identities (or conflicts thereof) in both sexes. There is both conscious and unconscious reinforcement of the child's imitation of his parent's (or model's) behavior. Johnson (1) illustrates this dramatically in her collaborative treatments of parent and child, noting that in every case a child with a fixation at the genital level had a parent with a similar fixation, and further illustrates that a common element in many of the identifications is the choice of specific symptoms based on observation of a parent symptomatology: fire setting as a family symptom for three generations: soiling and messiness by the mother and subsequently the daughters; and bestiality being explicitly offered as a symptom choice. Additionally, it is well known that the choice of a fetishistic object is often presented to the child by the parents, who then exalt its value and use it as a deflecting focal point for some of their own problems.

The role of the father per se has been addressed. Biller (2) found that the segment of the father's behavior which the boy can directly observe seems to have the most significance in terms of his masculine development. Liten and associates (3) believe that the mother's problems are the greater determinants of sexual pathology in the pregenital period, and the father's influence is stronger during the oedipal and later periods.

The parents may subtly define a pattern of sexual behavior, and the parental gratification from the child's behavior would perpetuate it. Liten and associates (3) describe a case of a transvestite whose father remarked (as the father did in the case which I described), "His dressing up is just a phase. I went through it myself." Emch (4) observed that "the acted out identifications exhibit caricatured reproductions of long-past parental behavior."

How may we then scrutinize with greater precision the role of the fathers in this identification process? Naturalistic experiments involving both normal and pathological development may provide some of the data on which to modify and reconstruct our theory. This type of work is exemplified by Cramer (5), who reported on the longitudinal study of three boys with particularly outstanding developmental progression from a group of 45 boys studied from age 4 to onset of puberty. One of the central findings in these outstanding boys was their strong masculine identification with their fathers, which became the core for organization of defenses in character traits. These outstanding boys very clearly had an intense desire to identify with their fathers, and took on their attitudes and values, shared their activities and coping styles, wanting to be exactly like their fathers when they grew up. The beginning of this identification with fathers was in the oedipal period and remained strong until the end of their puberty.

The area of both normal and developmentally deviant impacts of specific interactive and intrapsychic constellations of the father is largely unexplored. The specific sexual identity behavior, attachment, discipline, and their effect on family organization would seem critical. An example would be the very different motivational force impinging on identification: from fear of castration and identification with the aggressor being a primary motivator at one end of the spec-

trum, to love and affection primarily motivating identification at the other end.

Implications for future research are suggested in several areas. First, the age of onset of transvestism (or other sexual deviation), including the detail and circumstances of the first episode, whether being self-initiated, being cross-dressed by the mother, or after observation of this behavior in some important figure. The specific relationships with both mother and father and their interrelationship are critical. Transvestism may have several meanings as well as being multidetermined in an individual. I now have in analytic therapy a patient who began cross-dressing when his mother suddenly died at his age 10, and the dressing has been only in her clothes and served the purpose of the perpetuation of her image in his mind and denial of her death. The "bottom-line dynamic" of relieving castration anxiety by acting out the fantasy of the phallic woman with whom the man can then identify should receive increasing skepticism as a ubiquitous and primary pathological force in sexual deviation.

Other areas of study might include family studies, including naturalistic observation of sexual behavior, normal and abnormal, as well as data that the psychoanalyst can collect, such as the unconscious processes of childhood motivational influences that determine present behavior and fantasy. Close collaborative observations between therapists when both child and parent have been treated, especially focusing on the dynamic emotional interplay between child and both parents, may be fruitful.

Subjective and Objective Analysis of Patients

SIR: That tardive dyskinesia can be more than a nuisance and that it can threaten life is important information. Daniel E. Casey, M.D., and Peter Rabins, M.D., deserve credit for discerning this and sharing with us their report "Tardive Dyskinesia as a Life-Threatening Illness" (April 1978 issue).

I am alarmed, however, that practically nothing is reported about what this particular patient felt and thought or what she may have worried about, nor did there seem to be any inquiry into the possible connection between these psychological factors and her physiological signs and symptoms. Perhaps it was merely the editorial restriction to 1,000 words that deterred the authors. But in light of the currently raging controversy about the "medical model" in psychiatry (of which the Letters to the Editor section in the same issue is an eloquent example) I worry that the purely physiological approach of this report is an omen of things to come, if these are not already present.

Even from a purely biochemical point of view, the treatment of depression and some anxiety with chl[illegible] puzzling, unless one assumes that in 1958 [illegible] were the only widely known psychotropic me[illegible] why no attention to the obvious reactive (gr[illegible] the presenting symptoms? Why no concern th[illegible] recurrent anxiety upon reduction of medicat[illegible] ticipation of no longer seeing the doctor. p[illegible] remaining supportive figure in her widowhoo[illegible] so strange if her "separation anxiety" (th[illegible] analytic myth) reached extreme degrees on[illegible] that her (presumably) new and enthusiastic [illegible] termined to take her off medications? Cou[illegible] contribute to, or wholly explain, the more un[illegible] symptoms observed, e.g., irregular breath[illegible] (anxious people do swallow air), as well as th[illegible] retching (in itself possibly secondary to ac[illegible] watch a baby regurgitate if it is not burped[illegible] gastroscopy, barium swallow, etc., were giv[illegible] chiatric interview was reported.

Finally, all signs are attributed to tardive d[illegible] by a process of elimination (not of psychogen[illegible] ever) than by positive evidence. True, an e[illegible] cussion on how an imbalance of neurotransm[illegible] tered sensitivity of receptor sites could expla[illegible] tions is offered. Apparently ignored is [illegible] understanding the physicochemical mechanis[illegible] and symptoms of a psychological state (be th[illegible] pression, elation, or what have you) does no[illegible] need to be fully aware of the patient's subject[illegible] as well and to deal with it on an interperso[illegible] mean more than just "bedside manners" or "[illegible] chology"). In fact, it is the competence to de[illegible] special expertise of the psychiatrist.

My quarrel is not with the authors; my qu[illegible] ominous trend in psychiatry which, in the na[illegible] ing to the mainstream of medicine" would ma[illegible] and pillpushers of us all, for the greater glor[illegible] and the detriment of our patients.

EDMUND [illegible]
Cup[illegible]

Drs. Casey and Rabins Reply

SIR: We agree that psychiatry is uniquely [illegible] its special expertise in dealing with psycholo[illegible] ological dimensions of patients. To take sides [illegible] dualism argument both neglects the relevan[illegible] view and misses the important unifying co[illegible] beings. Patients are best viewed subjectively [illegible] uals with unique empathically understandabl[illegible] responses, and objectively, i.e., as organis[illegible] interrelated functional systems.

Issues of personality, psychological needs, [illegible] ation are crucial in the care of all patients, [illegible] assure Dr. Kal that we have attended to these [illegible] ever, the compelling aspect of this patient's [illegible] we emphasized in our report was the unusual [illegible] constellation of symptoms and their increasin[illegible] though her symptoms increased with anxiet[illegible] evidence that the etiology of her symptoms [illegible] psychological conflicts. To be blind to the [illegible] physiological nature of the findings that form[illegible] this case report could have led to more seriou[illegible] and psychological sequelae.

We disagree with the notion that psychiatry's "returning to the mainstream of medicine would make biochemists and pillpushers of us all, for the greater glory of 'science' and the detriment of our patients." Rather, returning to the mainstream of medicine should lead to better diagnostic criteria and improved indications for our available treatment modalities. The biological contributions to our advanced understanding of psychiatric illnesses have immeasurably been to the benefit rather than to the detriment of our patients.

PETER RABINS, M.D.
Baltimore, Md.

Generic Versus Brand Name Psychotropics

SIR: The spreading legalization of the substitution of generic for brand-name drugs, including psychotropics, is responsible for an escalating number of patients receiving generic rather than the prescribed brand-name drug from the dispensing pharmacist. In the case of tricyclic antidepressants, this practice can be hazardous because, as the Food and Drug Administration has stated in the Federal Register of February 17, 1978, "available data suggest that the various marketed brands of the same oral tricyclic antidepressant may not have comparable therapeutic effects" (due to bioequivalence differences) and "the substitution of a poorly bioavailable form in the regimen of a patient controlled on a fully available form would result in reversion to the depressed state."

I am gathering instances of 1) depressed patients who did not respond to initial treatment with a generic tricyclic antidepressant but did respond to a subsequently administered brand-name tricyclic antidepressant, and 2) depressed patients who responded to a brand-name tricyclic but relapsed when a generic form was substituted. I would be grateful if my fellow psychiatrists who have had patients adversely affected by treatment with a generic tricyclic antidepressant would share their data with me.

FRANK J. AYD, JR., M.D.
Baltimore, Md.

Bromism from Over-the-Counter Medications

SIR: In his article "Bromism: Alive in Well" (July 1978 issue) Ira Brenner, M.D., pointed out that neuropsychiatric symptoms can occur below the normally accepted cut-off point of 50 mg/100 ml. We have reason to believe that bromism is not a rare disorder and have recently seen a case here. The patient, a 33-year-old man, was admitted for treatment of a depression that had been intermittent and manifested by sudden episodes of his feeling "very depressed," which lasted minutes to hours and occurred several times weekly. The patient had had these episodes for approximately 3 months and had been treated previously in a hospital. He is now an outpatient and has been given adequate doses of tricyclic antidepressants, with no relief. The patient reported a history of diminished libido and decreased concentration over the previous 2 years, although he denied sleep or appetite disturbance, suicidality, delusions, or hallucinations. He was unable to perform his work as an engineer and was socially withdrawn from his premorbid life style. He had poor impulse control that was worse when he drank alcohol, which he used to self-medicate for his subjective depression.

Psychological testing showed that the patient had a verbal IQ of 124 and a performance IQ of 106. The Graham Kendall Memory Test reflected normal perceptual motor abilities. The Bender-Gestalt was normal. Neurological and physical examinations were within normal limits. All laboratory tests, skull series, and CT scan were within normal limits except for a bromide level of 42 mg/100 ml. The patient was kept in the hospital (medication-free) for 1 month, with resolution of his episodes of depression. The bromide level gradually decreased to 30 over 2 weeks. The patient did not evince any of the impulsivity that had been reported prior to admission, and his ability to concentrate appeared to return by the time of discharge. Short-term follow-up at 1 month has disclosed the absence of his previous symptoms on no medications.

The patient reported that he had been taking an over-the-counter sedative but was unable to remember the name; the bromide probably came from this source. After his recovery, discussion with the patient revealed that he had been feeling anxious about his job performance and started taking these over-the-counter preparations, which did not initially relieve his anxiety; he increased the frequency of ingestion as a way of attempting to get control of his anxiety. This behavior had continued for 7 or 8 months before admission and had not been detected by previous psychiatrists or in previous hospitalizations over the six months before admission. Contact with the patient's previous physicians revealed that they had appropriately asked him about any medication he was taking at the time they evaluated him, but the patient reports that he did not consider over-the-counter medications as the type of medication the physicians were asking about. This suggests that in all evaluations patients should be directed to inform the physician about all pills they are ingesting (including over-the-counter medications, vitamins, oral contraceptives, etc.) since the patients may not relate these to the reason they went to see the physician.

ROBERT H. GERNER, M.D.
Los Angeles, Calif.

Another Reason for Underutilization of Partial Hospitalization?

SIR: I would like to comment on the article titled "The Paradoxical Underutilization of Partial Hospitalization" by Edward B. Fink, M.D., Richard Longabaugh, Ed.D., and Robert Stout, Ph.D. (June 1978 issue). The authors conclude that the underutilization of partial hospitalization "appears to be largely attributable to the subjective discomforts of physicians and patients' families with this alternative treatment setting." The authors only briefly mention that there have been refusals of third-party payers to finance partial hospitalization treatment and do not seem to feel that it is important enough to include in their conclusions.

In a brief telephone survey of six major health insurance providers and state and federal medical providers I found that Blue Cross, Midland Mutual, and Medicaid (State of Ohio Welfare Department) will pay no percentage of partial psychiatric hospitalization; depending on the individual or group policy, Blue Shield and Travelers will pay no percentage of hospital bills and some percentage of physicians' bills; Prudential will pay some percentage; and Aetna will pay 50%–80% but does not cover meals. Medicaid (U.S. government for patients over 65 or disabled for 2 years or longer)

will pay no percentage of hospital costs but will pay physicians' bills. The results of this survey show that only two companies, Prudential and Aetna, will write some policies that cover a percentage of day hospital treatment. Blue Cross, Travelers, Midland, and most Blue Shield plans will not pay for partial hospitalization. I submit that the authors' conclusions that the underutilization of partial hospitalization is attributable to subjective discomfort on the part of the physician and patients to this alternative treatment are incomplete.

Another conclusion might be that it is an ethical response on the part of psychiatrists and psychologists not to have patients admitted to psychiatric facilities when insurance and family resources cannot cover the accrued bills (and it is rare to see patients pay for hospital services without the help of third-party payments).

CARL L. TISHLER, PH.D.
Columbus, Ohio

Dr. Fink and Associates Reply

SIR: Dr. Tishler's letter addresses a very important problem in partial hospital utilization; namely, that many health insurance providers do not pay for psychiatric treatment in a partial hospital setting. He contends that this is a more important reason for underutilization than those we emphasized.

In the day hospital described in our article, however, the lack of third-party payment for day hospitalization was not a problem. Prior to the establishment of our partial hospital program in 1973, extensive negotiations were completed between the hospital and Blue Cross/Blue Shield of Rhode Island, the major third-party payer in the state. On a trial basis, the insurance carrier agreed to offer its subscribers partial hospitalization coverage as an alternative to inpatient coverage. The agreement with the hospital included the condition that the hospital complete a treatment outcome study with 18-month follow-up data. The study has documented, to the satisfaction of Blue Cross/Blue Shield, that partial hospitalization is beneficial to patients and family members, as well as to the third-party payer. Partial hospital coverage now is a permanent feature of Blue Cross/Blue Shield contracts in Rhode Island.

Although the negotiations and the completion of the outcome study required extensive efforts on the part of the hospital administration and clinicians, it was judged that such efforts were worthwhile. Other psychiatric institutions have followed our early example, and many hospitals in the surrounding area discussed their specific third-party payer problems with us and learned of our experience. Several of these hospitals have by now successfully negotiated analogous arrangements with insurance providers. In contrast to Dr. Tishler's survey, our local Blue Cross/Blue Shield office reports that its affiliates in as many as 17 other states are providing coverage for partial hospital programs as of this date. (A complete listing is available on request.)

Dr. Tishler's letter also suggests that for ethical reasons clinicians should consider not admitting patients to partial hospital programs if third-party payers do not cover the cost of medical care. As documented in the introduction to our article (see references 1–4, p. 716), many clinicians and researchers contend that such a practice would not be in the best interest of patient care. Perhaps an alternative more productive than Dr. Tishler's would be to increase our efforts to educate the third-party carriers, as well as patients and their families, regarding the advantages of treatment in the partial hospital setting. The development of alternative clinical services which meet the needs of patients thereby would be fostered.

There is no doubt that the development of partial hospitalization programs presents many potential obstacles, as well as many significant ones. Our experience with Blue Cross/Blue Shield in this state, however, has been successful. We hope that our experience will continue to encourage the efforts of others.

Maladaptation in Prehistory

SIR: In "The 'Relief Effect': A Sociobiological Model for Neurotic Distress and Large-Group Therapy" (this issue) Marc Galanter, M.D., put forward a sociobiological model to explain vulnerability to neurotic symptoms. He argued that because affiliation with a cohesive group engenders a significant decline in distress, the adaptive value of this vulnerability may lie in assuring effective integration with a large social unit, thereby leading to a more adaptive social unit.

I recently put forward another hypothesis to explain human vulnerability to neurotic distress symptoms. My hypothesis is based on the notion that both adaptation and maladaptation are active processes which can be understood the concept of adaptive and maladaptive cycles. A maladaptive cycle, which includes neurotic distress, is based on the premise that failure may lead to failure. These ideas led to a hypothesis about the origin of neurotic maladaptation in prehistory. As natural selection operates on genetic differences, the two methods of warfare have magnified the impact of these genetic differences, thereby accelerating the weeding action of natural selection. This dual process would have accelerated the maladaptation of various animal species, including man.

Dr. Galanter's hypothesis and mine differ in that he refers to adaptive and maladaptive cycles, he refers to them in terms of a single continuum, the adaptive end of which overlaps with his is that of Price, who sees neurosis as playing an adaptive biological role (3). Both Price and Galanter view neurosis as promoting social behavior.

Dr. Galanter did not attempt to provide a sociobiological formulation explaining why very cohesive groups are more successful in contributing to a decline in neurotic distress. One knows that less cohesive families are more likely to generate neurotic distress symptoms in their offspring; one can differentiate between peer or family groups that are functional and those that are dysfunctional in terms of the support they provide for the members of the group. What is the sociobiological function of this difference? It is well known that when groups compete, those who win tend to show euphoria and those who are defeated tend to exhibit depression and anxiety. This even when representatives of groups compete. I would suggest that in prehistoric times the morale or cohesiveness of a group would have been a rough index of the biological fitness of the members of the group. The well-integrated peer group would have been able to provide greater support to their members than would the less well-integrated group.

This would be an illustration of inclusive fitness. For example, if the members of the group were on the whole not well fitted for survival, they would have been less successful in intergroup competition than those who were relatively well fitted for survival. In view of their poor morale they would have been less able to provide support for each other, so that the members of the group would therefore have been at an increased disadvantage. This would have tended to lead to a more rapid elimination of the latter group as a whole. On the other hand, groups who were better adapted would have been able to provide their members with more support, so that their chances of survival would have been increased. By promoting the rapidity of natural selection, this mechanism would have accelerated the evolution of early man.

The sociobiological model just described enables one to postulate an ideal family or peer group system which in a pretechnological age would have reflected a high level of biological adaptation. The structure of the ideal system in the past would have been designed to promote the adaptation and ultimately the survival of the individual family members.

It is my contention that sociobiology can illuminate our understanding of why some groups are well geared to promote Dr. Galanter's "relief effect" and that a delineation of the structure of these groups could also provide clinical guidelines in group and family therapy. In conclusion, it is noteworthy that Galanter, Price and I have independently arrived at related conclusions about the relevance of sociobiological principles in furthering our understanding of human neurosis.

Toronto, Ont., Canada

Dr. Galanter Replies

SIR: A useful perspective on the biological basis of man's psychiatric problems may lie in his evolutionary past. In this regard, Dr. Sloman raises an important issue by pointing to the availability of alternative sociobiological hypotheses to explain the adaptive value of neuroticism. His proposal also reflects the value of "crucial" experiments, in which alternate possible outcomes may exclude one or another competing hypothesis. In sociobiology of the higher species, however, difficulty in experimental manipulation means that we can, generally, only examine experiments of nature when they occur. In the study I reported, such an examination was made of a charismatic sect in an attempt to disconfirm the proposed "relief effect" hypothesis; however, the hypothesis was supported by an analysis of the empirical data.

Dr. Sloman has suggested that the evolutionary value of neuroticism lay originally in promoting more rapid elimination of poorly adapted individuals. This would presuppose significant ecological pressure in this direction, most likely due to competition for limited resources and expendability to the group of some of its adult members. The fact that neither experimental support nor rejection is available for Dr. Sloman's hypothesis reflects the difficulty in obtaining relevant naturalistic data but does not detract from the fact that any hypothesis must ultimately stand the test of empirical examination.

In addition, any mechanism proposed to persist on an evolutionary basis must be scrutinized with regard to its cost/benefit ratio in relation to group survival. This allows us to apply a measure of indirect evidence, even with our limited knowledge of the social ecology of early man. Using this approach, we are better able to evaluate hypotheses on human sociobiology on their a priori merits.

In applying this principle to Dr. Sloman's proposed mechanism, its adaptive value would hinge on the loss of the adults who were debilitated to the point of performing so little useful work that they detracted from the inclusive fitness of the group. On the other hand, this mechanism also implies an increased risk of mortality even to adults temporarily or partially disabled by neurotic symptoms. An increase in the loss of such viable individuals after infancy, however, would significantly detract from the adaptive capacity of any primate species, since a large portion of available labor is dedicated to prolonged nurturance and training of progeny. This prior investment means that adult mortalities come at considerable cost to the group. Indeed, it has been pointed out (1) that, for this very reason, in species with substantial parental investment in the young, mortality is generally concentrated in the earliest ages. I would therefore think that the evolutionary role of neurosis is best explained in a way which does not imply enhanced fitness based on increased adult mortalities.

Neurobiology and Dreams: Further Queries

SIR: I read with great interest the articles by J. Allan Hobson, M.D., and Robert W. McCarley, M.D., on "The Neurobiological Origins of Psychoanalytic Dream Theory" and "The Brain as a Dream State Generator: An Activation-Synthesis Hypothesis of the Dream Process" (November and December 1977 issues). I would like to comment on the psychological implications of their work from the viewpoint of recent contributions by Piaget.

The authors assume, as did Freud, that total isomorphism exists between the simultaneous physiological and psychological events of dreaming. Piaget (1) argues that the isomorphism between these systems is at best "partial," the physiological events being homeostatic whereas the psychological events are characterized by progressive equilibration, or "homeorhesis." Piaget (2) says that mental imagery is not "perceptual," in the sense of being an internally driven continuation of perception, but "quasi-perceptual," i.e., an internalized imitation of perception that is closely related to cognitive development as a whole.

Until REMs can acquire some degree of direction and organization as a result of their interaction with a sufficiently adapted intelligence capable of mental imagery (at the completion of the sensorimotor stage), there is no reason to assume that children (or cats, or opossums, in which REMs are even more prominent) experience the hallucinoid images synonymous with dreaming in the adult. Drs. Hobson and McCarley state that hallucinoid dreaming is the psychological concomitant of desynchronized (D) sleep; Piaget would say that activation, as undirected and unorganized motor excitation resulting from the autonomous process of nervous detoxification, exists before synthesis into dreams in early childhood and together with it only when the child develops mental imagery.

Dreaming assimilates reality to the ego, invariably distorting it (3). In psychoanalytic theory, this is called condensation, displacement, splitting, and symbol formation, suggesting that it is the work of the censor. Drs. Hobson and McCarley suggest that these phenomena are genotypically determined by the purely physiological, homeostatic activity of the brain stem. For instance, change of scene and time compression may be direct results of physiological changes in the generator system, but Piaget has shown that symbol formation is not explained on this basis (3). Like Hobson and McCarley, Piaget finds no need for repression, or for a censor, whose purpose is to disguise. Distortion in the symbols results from the excessive assimilation inherent in symbol formation. If there were no accommodation at all, however, there would be no images and certainly no conscious awareness of them.

In summary, dreaming seems to result from the necessary interaction of two relatively autonomous systems, the physiological activation system of the pontine reticular formation and the psychological cognitive system, which has a widespread neurological substrate. This explanation of dreaming, which is both modern and plausible, avoids reducing the psychological to the physiological while recognizing the partial isomorphism that exists between the two levels of organization.

Almost paradoxically, this composite dream theory permits one to salvage the psychological, wish-fulfillment part of Freud's dream theory if one extends the definition of "wishing" to include the free assimilation of reality to the ego.

Again, I applaud Drs. Hobson and McCarley for providing an important element in understanding dreams.

SIR: I would like to add to the commentary on the fascinating hypothesis set forth by Drs. McCarley and Hobson. Relevant to their activation-synthesis hypothesis of dream process is a recent paper by Gazzaniga and associates (1), who demonstrated in a callosal-sectioned patient two major, independent language systems in the right and left hemispheres. The right hemisphere, although not [illegible] pressive speech, could comprehend nouns [illegible] possessed the motor engrams necessary to [illegible] and pictorial commands. Of particular interest [illegible] ner in which the left hemisphere reacted to [illegible] sponse to commands presented to the right h[illegible] trials requiring that the right hemisphere initi[illegible] the left half brain was forced into a positio[illegible] responses of unknown origin. Yet in each tri[illegible] sphere provided a reasonable explanation fo[illegible] responses. The verbal system of the left he[illegible] fore attributed causes to the behavioral re[illegible] right hemisphere. For example, when the co[illegible] was flashed to the right hemisphere, the subje[illegible] back of his head with his left hand. When aske[illegible] ize the response, the patient (i.e., the left he[illegible] bally responded "itch." Thus the left hemisph[illegible] the response and attempted to characterize it[illegible]

This neural process, the mechanism of whic[illegible] can be viewed, in principle, as akin to the [illegible] brain stem stimuli by the forebrain in the drea[illegible] brain, in both cases, attempts to synthesize [illegible] cepts from incomplete data provided by p[illegible] Furthermore, it is probable that both synthes[illegible] are profoundly influenced by specific psych[illegible] and events.

This process of attribution by the verbal sys[illegible] hemisphere in waking and the elaboration of bi[illegible] uli during dreaming represents a major advan[illegible] understanding of isomorphisms between bi[illegible] processes.

New Ha[illegible]

SIR: Drs. McCarley and Hobson showed [illegible] worked the nineteenth-century discovery [illegible] servation of energy into his psychological mo[illegible] imagined flow rather than transduction of e[illegible] central nervous system. They observed that c[illegible] be cancelled in Freud's model and that Freud's [illegible] cal model is his physiological model in disguis[illegible] of "mind-body isomorphism."

I doubt that Freud simply incorporated neu[illegible] into psychological theory, as the authors clai[illegible] of clinical studies helped him to generate co[illegible] like symbolism, repression, and the unconscio[illegible] ed in "Preliminary Communications" (1) and [illegible] Hysteria" (2), which antedated the "Project" [illegible] tories were the substrate for Freud's view of [illegible] symbolic reminiscences of traumatic events. P[illegible] toms disappeared when repressed memories er[illegible] this start, Freud failed to see the importance [illegible] (cancellation type) as part of his neuron model. [illegible] Exner had mentioned it. Freud's clinical we[illegible] lured him away from the idea of inhibition beca[illegible] traumata failed to produce symptoms. Rather [illegible] model shaping his psychological model, Freud's [illegible] cal insights about symptom relationships may [illegible] him away from a more workable physiology.

The concept of psychic energy has been doubtful for years. No one has found this entity or measured it. Still, energy must be part of every working model—a mind model is no exception. Freud abandoned his search for connections between nerves and dreams but kept the psychological model. Drs. McCarley and Hobson have proposed a newer physiological model, asking for major changes in analytic theory. The pons governs dreams in their model. They suggest that dream content comes from cortical efforts to make "the best of a bad job" served up by pontine circuits.

Is mind-body isomorphism really any more applicable today than it was in 1895? Drs. Hobson and McCarley describe the way pontine neurons turn dreams on and off, but this describes the clock, not the time-teller. Dream content may be far removed from individual nerve functioning. For example, the authors suggest that the sensation of sluggish motion in a chase dream is adequately explained by perception of pontine motor repression; invoking a wish to be caught is superfluous. However, most dreams lack chases, and some chase dreams must lack retarded motion sense. How could automatic circuits let through a sense of motor repression only some of the time?

Freud's energy transmission model does not work as physiology, but the psychological model has much clinical affirmation. The principle of mind-body isomorphism must be applied with great care. Every modeler will want to use it sooner or later. However, pontine activity and dreaming may be no more related than a brick is related to the architecture of a brick building. New knowledge about one does not demand an automatic change in the other.

Drs. McCarley and Hobson Reply

SIR: We are pleased to continue the discussion of our papers (see Letters to the Editor, May 1978 issue). We are especially grateful for the presentation of additional data and theories relevant to our hypotheses. We will group our comments into three areas.

1. *Unifying physiology and psychology with information from bisected brains.* The paper by Gazzaniga and associates (1) is indeed of immediate and important relevance to our activation-synthesis hypothesis. These authors presented tests to the separately functioning hemispheres of a patient with a complete "split brain." When the right hemisphere was required to initiate motor acts, the left half brain was forced into a position of observing responses whose source was unknown. The left hemisphere proved particularly adept at providing an explanation for the responses, as if the response had been initiated therein, i.e., the left hemisphere conscious system accepted the response as its own act.

The activation-synthesis hypothesis proposes that one of the important elements of dream construction is the activation of motor pattern generators during desynchronized (D) sleep, including those normally responsible for many "automatic" motor behaviors such as walking and running. Although the paralysis of the output neurons during D sleep prevents the execution of these acts, the rest of the brain still receives the same information as if the act had occurred. The new information is that synthetic efforts of the conscious system may, in fact, structure this kind of information as if it had been initiated in the usual way. We have recently given several examples from dreams of how information from such motor pattern generators may be smoothly incorporated into dreams (2), and the above data show how the conscious system (i.e., subjective awareness) may come to accept this activity as its own.

A recent report on the dreams of patients with commissurotomies (3) is also relevant because it discusses a hypothesis attributing the distinctive form and structure of dreams to their being primarily a right (nondominant) hemisphere phenomenon. In this view, dreaming takes on many of the characteristics of the visual and form-oriented right hemisphere rather than the verbal left hemisphere. If visual dreaming were mediated in the right hemisphere, patients with commissurotomies should be unable to make a verbal report of the visual components of their dreams, since the disconnected verbal left hemisphere would have no access to the visual experience of the right hemisphere. This theory was not supported; characteristic and usual reports of visual dreams were elicited during D sleep periods from a subject with complete callosal and commisure sections.

2. *Isomorphisms.* Although developed independently, our use of the term "isomorphisms" stems from the same roots as Piaget's: the desire for an appropriate formalism to describe the relationship between biology and psychology, brain and mind. Our work is, however, at a more modest and empirical but more easily verifiable level than Piaget's. For example, we seek isomorphisms between dream sensations and the activation of various sensory systems, whereas Piaget seeks correspondences at a different level, e.g., between order structures in cognitive processes (e.g., the ordering of action sequences and perception) and order in biology (e.g., the ordering of the DNA code) (4, pp. 164–165). At the most abstract level of isomorphism, Piaget is working on the hypothesis that the logico-mathematical thought processes are developed by reflection and abstraction on the inherent organization of action and peripheral processes which, in turn, are derived "from nervous coordinations, and so on back to the most widely generalizing functions of life" (4, p. 342). We think the question of whether isomorphisms are partial or complete is open, but we would note that Piaget's emphasis on partial isomorphism may reflect the high level of abstraction at which he is working. We concur with Piaget that reductionism is not the way to relate brain and mind and that it is both important and necessary for biologists and psychologists to collaborate in the future.

We emphasize again that the principle of isomorphism, by definition, does not mean a "simple incorporation" or transformation from biology to psychology (or vice versa). We point to our earlier comments (Letters to the Editor, May 1978) on the strategic choice of models of phenomena. These comments also apply to the query about the direction of the mutual influence between Freud's psychology and his physiology. The critical point is that had Freud possessed our current physiological knowledge, he could not have conceived his physiological model as he did, which would have had

very important consequences for the isomorphic psychological model. It is important to note that Freud did not contradict any accepted physiological principle known in the 1890s in his model: inhibitory elements in the nervous system at that time were a tentative, developing, and unproven concept. Freud had distinguished company, including the great Golgi, in not including inhibitory elements in a nervous system model. Our conclusion is that the isomorphism principle works quite well, but one must continually alter either physiological or psychological models when data critical to one or the other isomorphic domains are proven wrong. The problem is that in early psychoanalytic theory the isomorphic psychological model was not altered as knowledge of physiology progressed (see our comments below on psychic energy).

3. Dream form and dream content. First, some metaphorical carpentry: we are not talking about dream "bricks," but dream "form," and the proper metaphorical contrast would be architectural form versus architectural content. On this subject of form and content Robbe-Grillet (5) commented,

> what makes the cinema an art [is that] it creates a reality with forms. It is in its form that we must look for its true content. The same is true for any work of art, of any novel for instance: the choice of a narrative style, of a grammatical tense, of a rhythm of phrasing, of a vocabulary carries more weight than the actual story . . . the initial idea for a novel involves both the story and its style; often the latter may actually come first in the author's mind, as a painter may conceive of a canvas entirely in terms of vertical lines before deciding to depict a skyscraper group.

Our contention is that emphasis on dream form goes to the heart of what is dreamlike in dreams. We are in accord with Freud that the sensing of the physiological phenomenon of dream paralysis accounts for the ubiquity of dream reports of paralysis. Such sensing of physiological data can be observed in other systems, as in this sleep laboratory dream report example (2).

> I was spinning, my body was spinning around. The circus performers put the bit in their horses and they spin around. The trapeze was spinning like that. Hands at my sides and yet there was nothing touching me. I was as nature made me and I was revolving at 45 rpm record speed. Had a big hole in the center of my head. Spinning, spinning, and spinning and at the same time orbiting. Orbiting what I don't know. I'd stop for a second, stop this orbit and spinning.

Here, both form and content are dominated by the sensation of whirling in space, probably derived from the sensing of vestibular activation, a phenomenon especially prominent during D sleep. One might ask why all of our dreams are not of paralysis and spinning or any sensation whose physiological bases are present during all D periods. First, one may point to genuine physiological differences from one D sleep period to another in the degree of activation. Second, the phenomenon is akin to that of conscious attention in general; it is common to have a continually present physiological input that is only intermittently or episodically noted. One may have a high temperature but be aware only episodically of feeling hot. We expect that a more precise answer to this query will be found in further investigations of the physiology and psychology of attention, a developing but incomplete area. We emphasize again that the distinctive features of dreams as contrasted to waking experience are isomorphic to the physiology: The preeminence of visual imagery in dreams is isomorphic to the preeminence of visual system activation, and the presence of the striking sensation of paralysis or spinning (or floating) is characteristic of dreams, not of waking, and is isomorphic to characteristic of sleep physiological events that are rare in waking.

4. Psychic energy. We believe this concept, more than any other, illustrates the need for continual interchange between biology and psychology, between brain and mind theory. Advances in physiology since 1895 have made untenable Freud's concept of "nervous energy," which was isomorphic to psychic energy. Unfortunately, the corresponding concept of psychic energy has been left unmodified. We are extremely skeptical that outmoded physiological theory can persist as an isomorphic base for psychological theory. We know of no case where an outmoded physiological theory serves as a respectable and useful psychological theory. There is every indication that many psychoanalysts are aware of the problems with psychic energy, as we have noted in previous communications. Our own notion is that psychology can do well without the concept of psychic energy but cannot do without a theory of motivation. We think motivational theory is strongest when related to biology and see the source of the particular vigor of psychoanalytic theory in its biological roots and its correspondence to interest in motivation—an interest that, until recently, was lacking in traditional academic psychology. We see future growth coming through efforts to link physiological and psychological processes thought to be critical to motivation.

5. Dream process and dream symbol. Piaget's descriptive of the dream process in *Play, Dreams and Imitation in Childhood* (6) has some intriguing relationships to activation-synthesis hypothesis of dreaming. Piaget was writing 1951 and therefore could not have known that mnemonic sensorimotor centers are directly and intensely activated from pontine source during D sleep. Yet Piaget's discussion of the fate of external stimuli and how they are formed or cleared might be taken as paradigmatic for what might happen to internally generated stimuli. Piaget notes that external stimuli impinging on the body are often not represented in the dream as being part of the dreamer's body because the dreamer's mental state is analogous to a baby in the early or not stage of development, i.e., lacking consciousness of the "ego" in the sense of being unable to distinguish self from nonself, inside from outside. (Incidentally but important, Piaget's anecdotal observations about the fate of external stimuli and their frequent representation in characters or objects outside the dreamer have been confirmed in a number of controlled sleep laboratory studies.) In the dream, as in the sensorimotor stage, there is a lack of coordination between the tactile-kinesthetic and the visual system, and since the dreamer cannot identify the body sensation as his own, he "seeks it were a visual correspondence, but since he is motorically passive and is even unaware that he is involved. In the inevitable constructing images, he has recourse to an "assimilation which offers some point of resemblance" (p. 32). Thus for Piaget, much of the visual material of the dream may derive from innate symbolic representation.

Obviously, in view of what is known today about the intense, direct, but internal activation of the visual system, it would appear that Piaget's view that the dreamer "can do nothing" is in need of revision. We do, however, note that the tendency of many areas in the brain to be reciprocally activated during D sleep may further the process of symbolic representation so eloquently described by Piaget.

There are other interesting correspondences and links between Piaget's work and what may be happening in dreams. For example, the process of coordinating sensorimotor schemata (both in the sense of Piaget's theories and in the physiological sense) with the visual world is extremely important. This is an area of intense investigation in physiology and, interestingly enough, much of this sensorimotor and visual coordination is being traced to brain stem neuronal activity. For example, some of the motoric "action schemata" (simple motor acts such as walking) described by Piaget have been shown to have a clear physiological substrate, and the concept of a motor pattern generator for these acts is a most useful one. Some of these physiological motor pattern generators may bear an interesting isomorphic relationship to the cognitive representations that the infant in the sensorimotor stage is working to develop. Piaget speaks of play as useful in development and of dreams as often showing processes cognitively analogous to those in play. Viewed from the physiological side, it may be that the activation of motor pattern generators and the visual system in D sleep is functionally important in furthering development and coordination of these systems, just as Piaget sees dreams as important in furthering the development of possibly isomorphic cognitive systems. It is clear that this is a rich area for investigation of isomorphic links between physiology and psychology.

Medical School Admission Screening by Psychiatrists

SIR: Psychiatrists have not been excluded from medical school admission screening because of the newness of the art, the isolation of the practitioners, or the advocacy of the practitioners, as Henriette Klein, M.D., and Emily Mumford, Ph.D., suggest in "The Bent Twig: Psychiatry and Medical Education" (March 1978 issue). If psychiatrists have been excluded, it is because of their medical colleagues' embarrassment over the extravagance of their claims of expertise and the dearth of data supporting such claims. Both of these faults also affect Drs. Klein and Mumford's paper.

The authors suggest that because medical students are becoming less sensitive, psychiatric and psychological testing should be used to screen applicants for medical school. Such screening is almost surely made illegal by the Federal Rehabilitation Act of 1974. Drs. Klein and Mumford essentially concede this point when they acknowledge that such testing is vulnerable to legal challenges, as grade points are not. I am currently representing one medical school student denied readmission after psychiatric testing. That vulnerability is not a simple prejudice against psychiatrists but a recognition by courts that no person should be denied medical school admission on the basis of decisions that are demonstrably unreliable and invalid and therefore subject to misuse.

Perhaps more important for readers of the *American Journal of Psychiatry*, Drs. Klein and Mumford totally ignore the substantial number of psychiatric studies collected by Professors Alan Stone and Alan Dershowitz which demonstrate quite clearly that psychiatrists and psychologists are "not especially qualified to prognosticate the success, failure or risk of a college, graduate school or job applicant" (1). It is worth noting that the views expressed by Professors Stone and Dershowitz were officially endorsed by the American Orthopsychiatric Association.

Drs. Klein and Mumford provide absolutely no data that contradict this conclusion. Although their paper is filled with references, only one is even arguably relevant to their proposal that psychiatrists screen medical school applicants, and it apparently concludes that psychiatrists can tell—after the fact—who has committed suicide.

Although the goal of more humane and sensitive physicians is one we all support, psychiatric screening of medical school applicants will not achieve this goal. I suspect it would instead deprive the medical profession of many sensitive and humane people who would have been exactly the type of doctor that Drs. Klein and Mumford want.

An Explanation for Seasonality of Births in Schizophrenia

SIR: A large American study of season of birth and mental disorder was recently published in the *Archives of General Psychiatry* (1), and a similar study was published in the *British Journal of Psychiatry* in 1974 (2). Both studies showed a highly significant excess of births in the first quarter of the year for people who later became schizophrenic. The excess was approximately 8% for January, February, March, and April. The American study corrected for small differences in month of birth for the general population and provided a comprehensive literature review. Both articles listed a number of explanations for this finding, but they seem to have missed the simplest and most plausible explanation.

The schizophrenic patients in both studies were born between 1920 and 1955. During that period, a large number of schizophrenics of childbearing age were institutionalized. A schizophrenic psychosis at that time probably meant a mental hospital admission lasting from at least three months to two years. Although the sexual activity of hospitalized schizophrenics is probably less than that of the nonhospitalized population, it certainly is not nonexistent. Male and female patients were on different wards but were permitted ground

privileges in good weather. It is well known to the staff of most mental hospitals that in the private areas of the grounds a fair amount of sexual activity takes place in good weather. In such cases, given the distribution of diagnoses in hospitalized patients, at least one of the two procreating adults, often both, would have had a schizophrenic disorder.

The excess births of schizophrenic patients in the months of January, February, March, and April could easily be accounted for by the offspring of only a small percentage of the thousands of hospitalized patients. If conception did indeed take place during the warm months (June, July, August, and September) then a transmission rate of only 3%–5% would account for the excess number of schizophrenics born the next winter and early spring.

Research on Attitudes Toward the Mentally Ill

SIR: In their article "Fear of the Mentally Ill: Empirical Support for the Common Man's Response" (October 1977 issue) John M. Lagos, Ph.D., and associates provided admirable, concise discussions of the literature on the dangerousness of the mentally ill and the implications of public attitudes for community treatment. One wishes, however, that the original empirical study presented in the article had been performed more rigorously.

First, descriptions of violent activity were based on the admissions records of 400 patients, apparently with no checks on their validity in cases where the alleged violent behavior did not occur in the presence of the admitting physician. Then, assuming without demonstrating that the notes were reasonably accurate descriptions of actual behavior, the authors concluded that perhaps the public has reason to fear mental patients as a class because a significant percentage of the sample was found to have been violent before admission to a hospital. However, there was no control group, an elementary necessity in a study that attempts implicitly to compare one class of persons (the mentally ill) with another (normal individuals). The degree to which the public fears any group must depend in part on base rates, and the claim that the public may have reason to fear the mentally ill is an unwarranted interpretation.

More than a third (36%) of the mental patients committed one form of violence or another, but an even higher percentage of nonpatients may also behave violently. If so, the appropriate conclusion would be that all of us have great reason to fear many people and even more reason to fear nonpatients than patients.

Studies on the dangerousness of the mentally ill have immediate relevance to the politicized debates about civil commitment. At a time when psychiatry is often attacked as being unscientific and insufficiently concerned with civil liberties, this study can only add power to the critiques. One wishes the authors had added a control group or simply limited the paper to a fuller review of the literature [illegible] of its implications.

STEPHEN J. MORSE, [illegible]
Los An[illegible]

Dr. Lagos Replies

SIR: Dr. Morse points out that the design [illegible] not include a check on the validity of the re[illegible] acts found in the hospital charts. This is true [illegible] tutes a definite limitation that further studies [illegible] to avoid.

Dr. Morse also notes that no control gro[illegible] show whether violent acts are equally preva[illegible] al population. Once again he is correct. How[illegible] suggest that patients were more violent than [illegible] ulation. We categorically stated, "These [illegible] substantiate the proposition that ex-mental p[illegible] violent than the general population."

It seems to me that Dr. Morse has no[illegible] What we tried to say was that the research [illegible] so narrowly focused that the twin issues of [illegible] and community fear have been denied full sc[illegible] We did not claim to have settled anything. R[illegible] were assembled to illustrate the inadequacy [illegible] paradigm for research on patient violence [illegible] new approach to the education of communi[illegible] lence among mental patients is an issue.

Dr. Morse implies that our article reflect[illegible] concern for the civil liberties of psychiatr[illegible] doubtedly, the interests of patients will be[illegible] understanding them better. Our work has [illegible] dimension to the study of violence amon[illegible] tients as well as to the education of comm[illegible] patient violence. It is my belief that this [illegible] that in the long run this work will contrib[illegible] liberation than to the confinement of psych[illegible]

JOHN M[illegible], [illegible]

Peptidergic Influences: Tip of the Iceberg?

SIR: I would like to make a few comm[illegible] the excellent article "The Opiate Recepto[illegible] Like Peptides in the Brain" by Solomon [illegible] (June 1978 issue). Dr. Snyder calls partic[illegible] somewhat surprising density of enkepha[illegible] rons in the globus pallidus, along with evid[illegible] way arising from cell bodies in the caud[illegible] terminals in the globus pallidus release [illegible] ronal populations in that site. The caud[illegible] globus pallidus are usually viewed some[illegible] regulators of motor behavior, which seems [illegible] the observation that the globus pallidus c[illegible] kephalin than any other part of the brain [illegible] zance of the almost inextricable relations hip[illegible] and emotion (1–3), it is apparent that such [illegible] pendent on and coordinated with a whole [illegible] states, such as attention, motivation, pl[illegible] pleasure.

There is good evidence that the extrap[illegible] shares rich connections with the neocortex [illegible]

key limbic structures involved in these states of the CNS. It is known that neuronal output of the corpus striatum to brain stem extrapyramidal neurons maintains a tonic inhibitory influence on them, suppressing their interaction on rostral thalamic and neocortical sites of action. This striatal tonic influence is funnelled to the brain stem, thalamus, and overlying cortex through the globus pallidus, the site of rich enkephalin transmitter release, as indicated by Dr. Snyder. The striatal outflow of suppressor type is enhanced by cholinergic synaptic influence and diminished by dopaminergic influence on an interneuronal system in the caudate putamen. It would make sense to have this striatal output modified in the pallidum by a peptidergic influence that lends, perhaps, expressive shape to motivated and emotionally determined motor behavior.

The corpus striatum, rich in enkephalin-containing neurons, may also play a role in neocortical arousal and attentional processes by means of enkephalin release in the outflow station, the globus pallidus. Administration of L-dopa to animals produces EEG activation and signs of behavioral stimulation in doses and time course correlating with increased levels of dopamine rather than norepinephrine. Activation of dopaminergic nerve terminals touching on the caudate putamen is believed to inhibit them, resulting in reduction of their suppressor influence on globus pallidus neurons, and to bring about indirectly, through reduction in a diffuse thalamic recruiting system, cerebral cortical arousal that facilitates attention and motivated behavior. That an enkephalin influence in the globus pallidus appears to be a rich one might suggest that an important peptidergic neurotransmitter system needs to be taken account of in addition to the better known influence herein of dopamine, acetyl choline, and γ-aminobutyric acid.

That the extrapyramidal system exerts an effector influence both on cerebral cortical and older cortical centers in the limbic brain and is in turn influenced by them appears to be a concept growing more clear through current neurobiological studies. The function of peptidergic systems, along with other neurotransmitters and neuromodulators, in information processing in such neural assemblies will be of great interest as data continue to be developed.

Dr. Snyder Replies

SIR: I certainly agree with Dr. Kiely that the well-known association of the corpus striatum with regulation of motor behavior does not mean that enkephalin in these structures does not have to do with emotional behavior. Indeed, the embryologic development of the corpus striatum closely apposed to the amygdala in virtually a single structure argues strongly for some contribution of the corpus striatum to feeling states. At the same time, one should not focus so strongly upon the traditional role of opiates in pain perception and affective regulation as to neglect other possible roles of enkephalin systems. John Hughes and Hans Kosterlitz specifically selected the term "enkephalin," derived from the Greek meaning simply "in the head," in order to free us from prejudices about the functions of this new neurotransmitter peptide. High doses of opiates and opioid peptides do produce muscular rigidity in animals quite similar to that produced by neuroleptic drugs and perhaps resembling the rigidity of Parkinson's disease. I suspect that enkephalin neuronal systems now being mapped in diverse areas of the brain may be involved in a large number of brain functions and that we have only begun to appreciate some of the most obvious.

Concurrent Validity of DACL Questioned

SIR: I was happy to have my attention drawn to the article "The Concurrent Validity of the Depression Adjective Check List in a Normal Population" (May 1978 issue) by Roger Christenfeld, Ph.D., Bernard Lubin, Ph.D., and Maurice Satin, Ph.D., because I was the Principal Investigator of record on grant MH–19966, which was partially credited in the footnote for support of this investigation.[1] (Grant MH–20681 also supported the study).

The authors restate the title's assertion toward the end of the article: "The overall findings of this study support the concurrent validity of the DACL(E) as judged by psychiatrists' ratings of depressed mood. . . ." A hasty reader might think that this statement meant that the DACL score will tell you approximately the same thing regarding a person's mood as you would learn if a trained research psychiatrist interviewed the individual and gave you a rating. Such an interpretation would be wrong.

The two research psychiatrists whom I selected and worked with rated 7 of 309 subjects at level 3 (mood depression as severe as that sometimes seen in patients being treated for depressions). Four of these had DACL scores of 10 or more, but so did 12 subjects who showed no evidence of depressed mood (and so did 21 people whom the psychiatrists rated at level 1 or 2, both less severe than level 3). By lowering the cut–off score to below 10, more of the level 3 classification rates get even higher. Using a score higher than 10 produces even more false negatives. These high misclassification rates lead me to conclude that the DACL is a poor indicator of what the psychiatrists were observing, a conclusion that does not agree with the assertion of validity stated by Christenfeld and associates. How can this be?

My figures on the high rates of misclassification that the DACL score produces could be anticipated from the figures reported by Christenfeld and associates. The mean test scores at the 4 mood levels differ by less than a standard deviation in table 2. The correlation coefficient of 0.35 reported in table 1 is statistically significant, but I do not think it signifies "validity." I would want a correlation coefficient to be about twice this size before I would judge an index

[1] I was also Director of the Psychiatric Epidemiology Research Unit in the New York State Department of Mental Hygiene, the resources of which were essential for the conduct of this study. Maurice Satin was a predoctoral trainee in psychiatric epidemiology at the time these data were gathered. Dr. Christenfeld was a member of the research unit team.

measure to be a good indicator of a criterion measure.

Indeed, I find it remarkable that the correlation coefficient is so low since this self-rating scale offers a series of adjectives to be checked if the subject feels they are suitable replies to "How do you feel today?"—adjectives such as blue, hopeless, dejected, forlorn, glum. The list reads like a thesaurus entry of synonyms for the word depressed. These same words entered into the verbal give and take between psychiatrist and subject during the interview. Many of the same verbal signals were thus used in both appraisals and I expected a closer relation than we found. After all, there are only a finite number of words in our language with which to communicate a depressed mood. I think Christenfeld and associates were right to use the psychiatric rating as a criterion because the trained observer had two advantages over any paper and pencil test. He could ask the subject to elaborate on the meaning of each word used, and he could observe nonverbal signals such as tone, manner, posture, and facial expression.

I think the authors put too much emphasis on the statistical significance of the calculated correlation coefficient between the DACL score and the psychiatric rating. I believe that only capricious reactions to the words used in both contexts could have produced zero order correlations of no statistical significance. For that kind of finding I would suggest an article titled "Mental Hospital Staff Used Affective Terminology Chaotically." That simply was not the way the helpful staff at Norwich Hospital went about the task of telling us about their current mood.

I am preparing a more accurate report of this investigation for publication in which I will point out what inferences I think can be drawn from the data obtained.

ERNEST M. GRUENBERG, M.D., D.P.H.
Baltimore, Md.

Dr. Christenfeld and Associates Reply

SIR: We were interested to read Dr. Gruenberg's opinion, although we find his letter puzzling on the face of it. Our article presented the correlations in a hospital staff sample of the DACL with other depression measures, most pertinently with psychiatrists' judgment of depressed mood. Gruenberg submits "I would want a correlation coefficient to be about twice this size. . . ." He has, of course, the prerogative of each reader to set his own level of acceptable correlation; whether one infers that the results are validating or invalidating is akin to calling a glass half-full or half-empty.

There is, as all know, a vast difference between a psychiatric interview and a pencil and paper test even when both focus on the same trait. The field of personality assessment is not known for high reliability coefficients, and we continue to regard the correlations we found as supportive. We do not, however, as Gruenberg suggests, necessarily view imperfect correlations as flaws in the questionnaire. A psychiatric interview gains flexibility and insight at the cost of introducing the vagaries of interpretation and interpersonal dynamics. For instance, in this study it may be plausible that the correlation of DACL and psychiatric rating is lower for females partly because the male psychiatrists interpreted the responses of women with some bias. Lacking ultimate criteria we rely on concurrent validation. All four of the instruments we used, as well as the psychiatric ratings, helped to clarify the concept of depressed mood.

Gruenberg's invocation of the "hasty reader" who might assume that the DACL is equivalent to psychi[illegible] for individuals involves a serious misperceptio[illegible] of this article. The study[1] was undertaken to [illegible] pressed mood scale that could be used epidemi[illegible] to describe patterns in populations, not in indivi[illegible] lation coefficients with a (heuristic) criterion [illegible] ly to what extent a scale can do this, and [illegible] individual misclassifications is not relevant [illegible] clear that the DACL is a research instrument [illegible] cal one.

The data from this study, collected in 1971, [illegible] source and allow a variety of analyses, a num[illegible] we have planned. We are pleased to learn [illegible] berg is also preparing a report, but the conc[illegible] will be "more accurate" is not justified by h[illegible] the present article.

Psychiatric History: Potential for Abuse

SIR: Regarding the "Position Statement on [illegible] Against Persons with Previous Psychiatric Tr[illegible] 1978 issue, Official Actions) I am glad to see [illegible] being given to this extremely important area. [illegible] my colleagues I have long felt that the oblig[illegible] forms declaring whether one has received ps[illegible] ment is both an invasion of privacy and a pot[illegible] covert or overt discrimination. A number of [illegible] have been quite ethical in other respects her[illegible] able about lying when presented with this [illegible] reason that leaving the question unanswered [illegible] mission of having received psychiatric treat[illegible] and, since the question is unjustified and [illegible] er, feel ethically justified in answering it in the [illegible] of course opens them to the accusation of [illegible] information.

I wonder, however, if the statement goes [illegible] particularly concerned about the following req[illegible]

> With adequate safeguards and with the [illegible] of confidentiality under a code of ethics [illegible] medical consultant should be able to ask [illegible] needed medical information from applican[illegible] termine whether the person is capable of [illegible] specific functions normally expected in the [illegible] which he or she is being evaluated. The [illegible] about diagnosis and history should not be [illegible] ed to anyone outside of the medical unit.

It should be evident to anyone who has wo[illegible] or government systems that the physician in [illegible] has a primary obligation to his or her employ[illegible]

him or her not to communicate with the employer about the prospective employee is asking too much. Furthermore, the safeguards regarding medical documents are by no means as airtight as we would like to think. Any physician who is entrusted with the task of "screening" a prospective applicant is primarily serving the company, not the applicant. His access to private and therefore potentially prejudicial past information is no different from the access of the potential employer. In my view, judgments should be made on the information available at that time, even if it means overlooking potentially troublesome material. The alternative is a return to the system we have now, wherein a person's medical history can be used against him.

A simple and effective way around the difficulty, which has already been adopted by a number of agencies, is to include a question asking applicants whether they to the best of their knowledge have any medical condition that would interfere with safe and successful discharge of their duties. A person who conceals such information would be appropriately subject to penalty. An example might be the willful concealment of uncontrolled epilepsy by a person entrusted with the operation of hazardous machinery or motor vehicles. I think it is fair to expect that individuals applying for responsible and sensitive jobs would have the integrity to reveal those problems which could interfere with the discharge of their duties. The responsibility should be left to the individual. No other system is acceptable in an open and free society.

I hope that others will respond and that the American Psychiatric Association will add its voice to those attempting to protect the rights of individuals.

Neurological Basis for Syndromes and Symptoms of Disordered Recognition?

SIR: The case of intermetamorphosis syndrome reported by Demetrios E. Malliaras, M.D., and colleagues (Clinical and Research Reports, August 1978 issue) has several interesting features, particularly those suggesting a possible organic component of the illness. An aspect that was not discussed is the patient's delusional notion that her theology instructor (the subject of her misidentifications) was in love with her, a symptom often linked with the name de Clérambault (1). That this association of delusional phenomena may not be entirely fortuitous is suggested by a previous report (2) of their coexistence, although in that case the misidentification was of the Capgras type. In yet another report (3), where symptoms of both delusional hyperidentification (intermetamorphosis) and hypoidentification (Capgras) were present, the author thought that "repressed erotic desires" were an important psychopathological factor.

Aficionados of the syndrome of doubles will also recall a case described by Capgras and Carrette (4) in which the patient made flagrantly erotic advances toward her father, whom she perceived as a "double." In this case, like that reported by Dr. Malliaras and associates, a number of features (false feelings of strangeness and familiarity, olfactory hallucinations, episodic outbursts of aggression, well-preserved affect, and lack of incoherence of either spoken or written language) suggest a psychomotor component to the illness.

A review of Flor-Henry's recent writings (5) on temporal-limbic laterality and psychopathology suggests a link not only between the phenomenon of disordered recognition and the nondominant temporal lobe but also between hypersexuality and the right hemisphere. Nondominant temporal dysfunction may also be reflected by the marked verbal-performance discrepancy of the patient described by Dr. Malliaras and associates. It is tempting to speculate not only that symptoms of misidentification and erotic delusions might logically coexist but that the common pathology might be localized in the nondominant temporal lobe.

More on a Neglected Problem

SIR: The article "Father-Son Incest: Underreported Psychiatric Problem?" by Katharine N. Dixon, M.D., and associates (July 1978 issue) was of great interest to me. We have seen a case in our child guidance clinic that involved two brothers, aged 15 and 9, who had been used sexually by their father for at least 4 years, with their mother's full knowledge. The case came to our attention after the older boy informed his minister of his experiences.

Needless to say, the case presented serious management problems. The parents had maintained a conspiracy of silence for years and were enraged that this matter had come to the attention of people outside the family. Although the case was reported to the Child Protective Services as one of child abuse, the court made only a mild recommendation that the children obtain psychotherapy, a suggestion the parents angrily rejected.

Like the cases reported by Dr. Dixon and associates, this one emphasizes the extreme delicacy and complexity of such situations. I hope others in the field will be alerted to the existence of a problem that has been neglected. Dr. Dixon and her coworkers have performed a valuable service through their paper.

Medical Information Card for Patients Taking Lithium

SIR: At the Genesee Mental Health Center, we recently designed a wallet-sized information and warning card for our patients who are taking lithium carbonate. The card, which is analogous to those carried by patients taking disulfiram, was designed to alert these patients and their physicians

about the unique cautions that must be observed when patients are on maintenance lithium therapy. In addition, the card serves to inform others (e.g., family, ambulance drivers, police officers) about certain symptoms of lithium toxicity so that they can be recognized and medical evaluation and treatment can be instituted without unnecessary delay. One side of the card contains the following information: "I am on lithium carbonate. At any signs of diarrhea, nausea, vomiting, visual disturbance, tremor, unsteady walk, drowsiness, weakness, slurred speech, or mental confusion, please call my therapist." The phone number of the center and of an emergency room are then given. The reverse side gives the patient's name, address, and phone number, the name of his or her primary therapist, and a list of incompatible drugs (diuretics, sodium, potassium, and weight reduction pills).

We would be happy to hear any comments that readers might have about this idea.

Procedures for Taste Aversion Therapy for Alcoholism

SIR: Taste aversion therapy, one of the earliest attempts to apply experimentally derived principles of learning to clinical treatment (1), involves the pairing of the sight, smell, and taste of alcohol with the effects of an emetic. Recent basic research into the acquisition of taste aversions (2) has led to suggestions that taste aversion therapy be used more frequently (3).

The most widely used emetic in alcohol aversion therapy is emetine HCl. A frequently used regimen[1] consists of 5 treatments over a 10-day period. The oral dose of emetine is 100 mg per session, and the I.M. dose increases from 52 to 78 mg. The total treatment dosage during the series is 345 mg I.M. and 500 mg p.o. Rollo (4) has stated that emetine dosage should not exceed 60 mg/day I.M. or 600 mg I.M. in 10 days. Thus this treatment exceeds the maximum recommended daily emetine dosage and, depending on how much of the oral emetine is absorbed, approaches or exceeds the maximum recommended total emetine dosage over a 10-day course.

In attempting to develop a more conservative regimen, we found that lower dosages failed to produce reliable emesis, which is crucial to this treatment because of the quantity of alcohol consumed during conditioning. Syrup of ipecac, a much safer emetic, did not seem to produce good conditioning, perhaps owing to the short duration of its effects.

Currently we employ both 20 ml of ipecac p.o. and 42 mg of emetine I.M. The ipecac produces reliable emesis and the emetine prolongs the malaise. Strong aversions develop, but none of the symptoms of emetine toxicity (hypotension, precordial pain, tachycardia, dyspnea, and ECG [illegible] has been observed.

As in the more widely used procedure, [illegible] ephedrine are also given in the injection with [illegible] The pilocarpine dosage increases across sess[illegible] 18 mg, and the ephedrine dosage increases fr[illegible] Pilocarpine prevents the absorption of alcoh[illegible] small intestine by closing the pyloric sphinc[illegible] edrine protects against shock. In some cases [illegible] essary to reduce the pilocarpine dosage bec[illegible] pleasant side effects (e.g., abdominal cramp[illegible] utes after the oral ipecac and the emetine inj[illegible] are given about 2400 ml of a variety of alcoh[illegible] The inpatient course of 5 treatments is follo[illegible] patient treatment sessions over the next 6 mo[illegible]

Preliminary results of a clinical research p[illegible] in progress suggest that taste aversion the[illegible] adjunctive therapy in a comprehensive alcoho[illegible] tion program. Additional information on the [illegible] cedures may be obtained from the authors.

BOOK REVIEWS

The Psychological Society: A Critical Analysis of Psychiatry, Psychotherapy, Psychoanalysis and the Psychological Revolution, *by Martin L. Gross. New York, N.Y., Random House, 1978, 354 pp., $10.95.*

Psychotherapy is thought by some critics to be the Achilles' heel of contemporary psychiatry. Ever since Eysenck, in a 1952 monograph, claimed to have proven that the results of psychotherapy were not any better than no therapy at all, similar iconoclastic attacks have appeared periodically and have followed certain predictable patterns. For example, it has been charged that dynamic psychotherapy is useless; that if it works at all, it does so only through suggestion; that its favorable outcomes are the results of spontaneous remissions; that it does as much harm as good; that its presumptive scientific basis is pure hogwash; and that psychiatrists are simply twentieth century versions of primitive tribal witch doctors and their therapies depend on a similar kind of myth and magic.

The Psychological Society is the latest and one of the more sophisticated of this critical genre. Gross, a well-known editor and writer (*The Brain Watchers* and *The Doctors*), has done a good deal of research into psychiatric literature and has interviewed many psychiatrists and psychologists in the course of preparing this book. He has come up with a wide-ranging and hard-hitting attack on all dynamic psychiatry and particularly on Freudian psychoanalysis, which he considers to be the ideological wellspring of such psychiatric thought.

Gross's thesis, essentially, is that our society has been overpsychologized to its great detriment. Psychology (and psychiatry) has become "an art, science, therapy, religion, moral code, life-style, philosophy, and cult." The quest for an idealized "mental health," he asserts, has created self-doubt in millions of people who have been labeled as "neurotic" because they reflect the ordinary anxieties and insecurities of everyday living, and who are then subjected to an essentially useless variety of psychotherapies.

The bête noir behind this unhealthy state of affairs, according to the author, is psychoanalytic theory, which is attacked as a totally fanciful, unvalidated, and unscientific creation of Freud, whom Gross describes as a naïvely superstitious, mystical, and neurotic man.

Gross asserts that psychiatrists and psychologists, building on this dubious foundation, have put themselves forth as experts ("new seers") on a wide variety of human events, in effect replacing the oracles and prophets of old. He holds up to ridicule the often conflicting and mutually contradictory "authoritative" statements made by psychiatrists and psychologists about crime, criminals, politics, and international affairs, no less than statements about psychosomatic diseases, cancer, and homosexuality. He attacks theories about the psychogenic origins of the psychoses as being totally without merit and asserts that the influence of psychoanalytic theory in childrearing and in education has been harmful and misleading. Indeed, he quotes with obvious approval a characterization of this influence as "the psychological crime of the century."

The book is not to be lightly dismissed, however. Its views are buttressed by quotations from numerous psychiatrists and psychologists, many of outstanding eminence. Many of its criticisms are justified and cogently point up some of the soft spots in both psychiatry and clinical psychology—unwarranted promises, exaggerated claims, unscientific theorizing, fanciful analyses of dead historical figures, and unethical psychologizing about living ones. Where the book falls down is in its heavily biased and grossly (no pun intended) one-sided point of view. The author's view of human personality and psychopathology is that they are almost totally determined by genetic factors. Although he pays occasional lip service to the interplay of life events with these factors, his bias is so strongly biological as to be practically a twentieth-century caricature of nineteenth-century psychiatric thinking. Gross denies the existence of unconscious psychological elements and replaces them with "gene-determined neurological-biochemical circuitry." Reactions to love, adventure, threat, sex, and friendship may be "partially learned," he concedes, but are more importantly attributed to "thousands of protein-coded genes each of us has been endowed with since the moment of conception." Homosexuals are all "born that way." Neurosis is just a "Freudian fantasy," and the symptoms ascribed to it are more often due to "physical sickness." The psychoses are all due solely to biological factors and will eventually be prevented and cured by biochemical means alone. Dreams are merely accidental offshoots of neural activity and "have no particular meaning." Infantile and childhood sexuality are myths. "The human child is generally a non-sexual being." The child's personality has little or nothing to do with patterns of upbringing; it is almost entirely due to "temperament, nature, constitution, [and] inborn traits."

The author, moreover, like most intemperate critics, makes the error of throwing the baby out with the bath water. To dismiss the totality of Freud's contribution as a massive and harmful fraud perpetrated on an entire society is to lose all historical perspective with regard to that contribution. The ad hominem attack on Freud's personality is unworthy of the author and has no bearing on the value of Freud's work. Even if some of Freud's metapsychology has indeed proven to be in error, it still constituted a revolutionary breakthrough in its time and paved the way for more sophisticated later theories. In addition, Freud's formulation of a technique for studying psychological processes by psychological methods was a vitally important methodological advance that significantly furthered our understanding of human behavior and motivation.

Most of the criticisms that Gross advances come from psychiatrists and psychoanalysts themselves, pointing out errors and weaknesses in previous theory. Such dissensions are an intrinsic aspect of the scientific method, and similar criticisms could be compiled in any other field of science. Even so, however, almost all of the experts whom the author

chooses to quote (occasionally out of context) reflect a particular point of view, and Gross makes no effort to give a fair hearing to differing views.

Most of all, the one-sided and simplistic biological bias of the book does a massive injustice to the sophistication of biopsychosocial approaches and contemporary systems thinking in modern psychiatric theory and practice. To minimize the importance in human development of interpersonal life experiences and the social matrix in which they take place is just as egregious an error as it would be to ignore or minimize the importance of the biological factors involved. By the same token, to equate contemporary efforts at scientific psychotherapy with the magical incantations of the primitive tribal shaman is equally fallacious. The fact that they both achieve roughly equivalent results in some instances is quite beside the point. Ancient herbal medicines may cure some ailments just as well as modern antibiotics, but only by pursuing the methods of science can we hope to achieve the rational breakthroughs that lead to significant scientific advances. Continuing our efforts to rationally understand the sources of human emotional disorders and to treat them on the basis of such reasoned understanding is in the finest tradition of science. Whatever the limitations of our present knowledge, there is no reason to doubt that these efforts will ultimately be successful.

JUDD MARMOR, M.D.
Los Angeles, Calif.

The Technique of Psychotherapy, 3rd ed., Parts 1 and 2, *by Lewis R. Wolberg, M.D., New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1977, 1,301 pp., $69.00.*

It is a brave person indeed who would undertake to write a comprehensive textbook of psychotherapy, a field that, to quote the author, is "balanced precariously on the pinnacle of profound ambiguities. What seems like the truth of today may be the exploded myth of tomorrow" (p. 842). Dr. Wolberg accepted the challenge about a quarter of a century ago, and the appearance of this third edition is the measure of his success in meeting it. The size of the book itself indicates the magnitude of the task—it contains more than 1,300 double-column pages of text and more than 3,000 references.

The author succeeds in encompassing the chaotic field of psychotherapy by organizing it around a guiding concept. Although this concept is nowhere explicitly stated, it is clear that the author's basic conceptualization is a flexible psychoanalytic one. According to this model, other things being equal, the definitive treatment for neuroses and personality disorders is dyadic therapy based on efforts to bring into consciousness and thereby resolve unconscious conflicts and motivations, with special emphasis on handling the transference. This is termed "reconstructive therapy" in that, when successful, it is believed to achieve alteration of character structure and expansion of personality growth. More modest goals, which have their legitimate places, are supportive and reeducative therapies.

There is no convincing evidence that any forms of psychotherapy, including psychoanalysis, are capable of significantly restructuring personality, or that analytically oriented approaches produce more profound personality changes than other techniques. Still, it is hard to think of any better way of bringing order into the field of psychotherapies, and the author's framework would probably gain more general acceptance than any alternative. Wolberg manages to force most current psychotherapies into his co[illegible] even though this creates some unlikely bed[fellows] surgery and sociotherapy, for example, [illegible] forms of supportive therapy, while "Hare K[rishna] havior therapy are both classed as reeducat[ive] impose order also finds expression in a pl[ethora] tables, and charts that provide varying degr[ees] tion.

Given the author's orientation, the actu[al] volumes cannot be praised too highly. The [first] of extant therapies consists of concise, balanc[ed] with due consideration of strengths and weak[nesses] strating that the author has not only read b[roadly] writings of their proponents. It is, moreover, [also] clusive and up-to-date, omitting, to my know[ledge] approach, a self-help program with somethi[ng] known as reevaluation counseling.

The detailed, play-by-play descriptions of [psychotherapy] therapy, illustrated by many transcripts of sess[ions] views, are obviously based on extensive and [clinical] experience. Within a broad analytical framew[ork] tive, flexible approach that uses a variety of [techniques] techniques when appropriate. Descriptions [of] group, and family therapies, although consc[iously] tailed, are lucid and authoritative. Various [special] matters, among them evaluation of psychotic [patients] of emergencies, and community mental hea[lth] attention.

All in all, if it were possible to write a de[finitive] of psychotherapy at the present juncture, this [would] its encyclopedic coverage and extensive b[ibliography] cluding texts, films, and tapes, it is an ind[ispensable] ence work, and its detailed, clinically astut[e] constructive therapy provides an excellent [guide] remains the most widely used American a[uthor] undoubtedly maintain the deservedly pre[eminent] established by the earlier editions.

The Anatomy of Hallucinations, *by Fred H[oyle] cago, Ill., Nelson-Hall, 1978, 226 pp., $16.9[5]*

This unusual, scholarly volume was wr[itten] roanatomist who was Papaz' last Ph.D. studen[t] studied under and worked with many fam[ous] whom he dedicates his book. As a scholar J[ohnson] references with extracts from these writings [and] he has read them all and digested their cont[ents]

The term "anatomy" is not meant to in[dicate] cal descriptions but mental *processes* that o[ccur] rological circuitry, about which little is [known] theless, investigators have determined that [hallucinations] are accompanied by subvocal physiological [activity] inner speech that usurp normal inner speech.

Johnson quotes and outlines a long list of [persons] history of our world whose hallucinations [were] creative or destructive, including Hitler, Muss[olini] anese war lords. Many who seem healthy s[uffer] vocal speech in the form of hallucinations—[their] own thoughts as if they were spoken. For a s[ample] son quotes the observations of others indicat[ing that] hallucinators can hear the silent auditory ha[llucinations]

others confined within the same institution and also suffering from schizophrenia. Picture two patients with blank faces and immobile lips talking and listening to each other on a nonverbal level! Not only schizophrenic patients but hysterical patients and depressed psychotic patients may hallucinate. This, in my experience, is hard to teach because students seem to define hallucinations as a necessary symptom of schizophrenia. Also, hallucinations are painful for some and pleasurable for others.

This volume must have taken years to compile, especially since the author is an anatomist and not a clinician. He has succeeded ably in a scholarly product. He reminds me of an examiner for the American Board of Psychiatry and Neurology who, some years ago, asked his examinees, "I am hallucinating—prove it!" Now the answer would be, "I am not, so I cannot hear you." This is an informative and scholarly book.

ROY R. GRINKER, SR., M.D.
Chicago, Ill.

The Psychiatric Halfway House: A Handbook of Theory and Practice, *by Richard D. Budson, M.D. Pittsburgh, Pa., University of Pittsburgh Press, 1978, 274 pp., $10.95.*

This is an uncommonly well-written, concise, but complete book. It is a pleasure to read. The author is correct in saying that it "approaches the ideal of a general textbook on the subject of halfway houses." In a detailed, logical, but succinct manner Dr. Budson shares his exceptionally broad experience in working with and developing halfway houses. While at Harvard Medical School he worked as a student volunteer with patients at the Metropolitan State Hospital. After finishing his psychiatric residency, he established a halfway house and later became Director of Community Residence Programs for the Commonwealth of Massachusetts. Thus, with equal authority he can discuss the relationships of patients in group meetings in the halfway house and the problems of developing state laws and regulations that promote high-quality community facilities while not throttling their development with bureaucratic regulations.

The first part of the book, titled The Development of an Ideology, discusses the impetus and need for the halfway house, its relationship to the community, and its many functions analogous to the family in the home and the community. The author also discusses moving out of the halfway house into nonsupervised living. "The Halfway House As a Family-Model Social System" is a chapter especially worth reading. The family has a responsibility for seeing that its members carry out tasks that are appropriate to their age, abilities, and position within the family. In mental hospitals, most tasks are the exclusive province of the staff and thus patients are deprived of the opportunity to assume responsibilities that would enhance their growth and development. In the halfway house, as in the family, there is appropriate sharing of tasks and responsibility. This is one of many striking differences between it and a mental hospital. The author also spells out the responsibilities of a halfway house and its inhabitants to the community and to themselves and shows how these are similar to family responsibilities. The halfway house must be part of the community in which it resides and must understand the laws and regulations of that community.

In "Legal Issues, Standards, and Regulations," the author states that "it is essential that standards not be so stringent as to compromise the essential programmatic characteristics of the community residence." For example, standards that require too many staff for around-the-clock service and too strict adherence to building codes designed for institutions can cause a program to be expensive, unworkable, or counterproductive in that it perpetuates the institutional system it was designed to replace. Perhaps the greatest challenge of our times is to set standards that are essential for the control and upgrading of human services in such a way as to allow these services to function in a humane and therapeutic manner. The author provides a discussion of the rules and regulations in Massachusetts and compares them with those of other states.

The short and to the point chapter "Community Entry and Zoning Requirements" is essential reading for anyone wanting to establish a halfway house. It contains good advice on how to avoid many of the pitfalls that have defeated the best efforts of those who want to help the mentally ill reintegrate into the community. The nitty gritty of the planning and operation of a community residence is discussed in a manner in which the pertinent details take precedence over wordy discourse. It is obvious that the writer knows what he is talking about. He not only shares his factual knowledge with the reader but also is able to communicate an affective experience in an objective and helpful way. This especially comes through in discussions of the group meetings of house members.

My only irritation with the book is that bad practices in large mental hospitals are blamed on the medical model. The fact that bad medicine may be practiced in some hospitals because of inadequate funds and inadequate staff is not necessarily the fault of the medical model. Some doctors might practice bad medicine, just as some authoritarian, custodial types of halfway houses might promote regression rather than social integration. However, my objection is a minor one and does not detract from the excellence of the presentation and the material. This book exemplifies the virtues of the old-fashioned idea that a book should be written by a single author who says what he needs to and stops.

ROBERT L. LEON, M.D.
San Antonio, Tex.

Epidemiological Approaches in Child Psychiatry, *edited by P.J. Graham. London, England, Academic Press, 1977, 397 pp., $19.50.*

This volume is welcome as an initial systematic attempt to examine and evaluate epidemiological approaches in child psychiatry. It is the first presentation in a single volume of data and issues in a field that is in its inception. Few large population studies have been done in child psychiatry. Meaningful epidemiological work requires the development of interview and questionnaire schedules for which validity and pertinence are both satisfactory. At this point, valid and reliable instruments for screening populations of children are scarce. The lack of standardized clinical assessment methods presents serious problems of comparison from one geographical area to another and from one period to another. A significant study of a representative population also requires the definition of the group sampled by the population, the demonstration that the screening methods have a low degree of false positives and false negatives, and the clarification of the pertinence of the findings by studying a subsample in depth.

This volume consists of a collection of papers given at a symposium held in October 1976. The participants came from six European countries and Canada, although the major representation was from England. In such a symposium one must expect that the individual contributions will be of uneven quality—and this is the case here. However, the contributors include a number of leading research workers in the field, among them Michael Rutter, who chaired the symposium, and Philip Graham, who edited the volume and summarized the implications for prevention.

The chapter by Rutter on methodological considerations and the one by Lorna Wing on the use of case registers are deceptively simple in their presentation. These chapters represent sophisticated and knowledgeable discussions of these basic issues for large-scale studies. Both the novice in the field and the expert will find these papers valuable.

The body of the volume is organized developmentally, with sections on early parenting, the preschool child, middle childhood, and adolescence. A wide range of topics is covered, including useful discussions of child abuse, the search for predictive features in "at-risk" babies, the behavioral screening of preschoolers, and the short-term outcome of problems in this age group. There are two interesting comparisons of psychiatric disorders in urban and rural settings: one in 6-year-olds in Denmark and the other in adolescents in Norway. A British study examines correlates of behavioral deviance in 8-year-olds, and a German study examines the correlates of delinquent behavior in youngsters under 14 years of age.

The final sections deal with areas of special interest. In a chapter on the psychiatric aspects of sensory disorders, Freeman, from Vancouver, Canada, gives an organized summation and critique of the confusion of terminology and data in this field. Bohman, from Sweden, presents a tightly written and well-organized overview of studies of adopted children, focusing on social and genetic influences on development. His discussion emphasizes the value of epidemiological data for programs of prevention.

The linkage between epidemiological research and prevention is emphasized by Graham in his final overview chapter. To quote from his summation,

> It will be clear that, although in some rather limited areas (mainly those of more purely medical concern) guidelines for preventive action can be laid down with some confidence, for most conditions, further research and investigation is necessary before this stage can be said to be reached. . . . What has so far been lacking in these endeavors is an epidemiological approach with examination of the impact of changes in social or educational policy, or planned intervention on the rates of disorders in a population.

This volume makes a significant contribution toward this goal.

STELLA CHESS, M.D.
New York, N.Y.

Models of Madness, *by Erica M. Bates, Ph.D. Lawrence, Mass., University of Queensland Press, 1978, 175 pp., $16.95.*

The author divides the book into two parts. In the first she deals with the popular stereotypes that make up the models of mental illness in modern Western society [illegible] effects of labeling people as mentally ill. In t[illegible] she discusses her research, in which she atte[illegible] out just how people in an urban Australian [illegible] mentally ill.

The first part of the book is really a histo[illegible] attitudes toward deviant behavior. The autho[illegible] development of the medical model as a reac[illegible] gious or "accursed" model. From this grew [illegible] el, modified by the inclusion of the "sick [illegible] people needing medical attention. The medica[illegible] includes community psychiatry, with attempts [illegible] psychiatry. The sociological model views [illegible] deviant social role, emphasizing that the s[illegible] rather than the actor is the critical variable [illegible] garding labeling and disposition.

The author then reviews the antipsychi[illegible] tional modes of Szasz and Laing, in which [illegible] change or modify deviant behavior is seen as [illegible] violating the patient's rights. The education[illegible] as the introduction of coping skills to the cli[illegible] an overview, the author sees four perspectiv[illegible] the goodness/badness dimension, the he[illegible] sion, the educated/miseducated dimension, a[illegible] equality/power dimension.

The second part of the book is the resear[illegible] of Australian urban populations as to the n[illegible] illness, the cause of mental illness, what s[illegible] about it, who should do it, and what are the [illegible] These attitudes are determined by a questi[illegible] thor provides numerical tabulations of the r[illegible] various questions.

The first part of the book is a good review [illegible] changes in the attitudes of psychiatrists tow[illegible] ward deviant behavior. The second part is [illegible] what modern Australian city dwellers th[illegible] behavior. The book is of moderate interest t[illegible] mental health professions. The research sho[illegible] to politicians, statesmen, and those who w[illegible] It reinforms us of the generally naïve attitudes [illegible] populace.

MAURICE J. B[illegible]
Ro[illegible]

International Encyclopedia of Psychiatry, Ps[illegible] analysis, and Neurology, 12 vols., *Benjamin [illegible] tor-in-chief. Division editors: Jules H. [illegible] Psychiatry; Joseph M. Notterman, PhD., [illegible] chology and Related Fields; Gordon F. De[illegible] George Stricker, Ph.D., Social, Developm[illegible] cal Psychology; Albert J. Solnit, M.D., [illegible] M.D., Psychoanalysis; and H. Houston Me[illegible] Abner Wolf, M.D., Neurology. New York, [illegible] trand Reinhold Co. for Aesculapius Publis[illegible] pp., $675.00.*

The task of reviewing an encyclopedia [illegible] dable and at worst futile. The venture unde[illegible] man is of heroic proportions. This set of vol[illegible] fields of psychiatry, psychology, psychoan[illegible] rology. To a surprising degree the encyclope[illegible] up to its name. This is both its strength and [illegible] tion. Virtually anything you wanted to know [illegible] to ask is to be found in this encyclopedia [illegible]

does not lend itself to leisurely reading, as does a good textbook. In my judgment it is exculsively a reference volume and a very complete one at that.

The editors have done a great deal of work in an attempt to unify the style so that the unavoidable differences between entries are minimized. All of the topics have a few bibliographical citations that can assist the reader in further explorations. No single topic is treated in excessive detail. The editors have placed stringent controls on the length of the entries in an effort to limit the size of the finished product. This was a necessary condition, but it leaves some of the topic treatments less than fully satisfying.

There are many virtues to be found in this encyclopedia, including the fact that it is a single source of much diverse information. The editors and authors selected to participate in this effort represent a remarkable array of talent never before brought together in a single undertaking. There is hardly a well-known figure who is not to be found in the pages of this encyclopedia. The information presented on the various topics is succinct and readily available. Nevertheless, it is unrealistic to expect that most practitioners will turn to such a set of volumes for assistance in their day-to-day educational needs. An encyclopedia is not likely to be used as a daily source of information. It has a special place and a special value. To the extent that any single encyclopedia can encompass these four fields, this effort has achieved that goal remarkably well.

ROBERT CANCRO, M.D.
New York, N.Y.

The Epidemiology of Heroin and Other Narcotics. NIDA Research Monograph 16, *edited by Joan Dunne Rittenhouse, Ph.D. Rockville, Md., National Institute on Drug Abuse, 1977, 247 pp., no price listed.*

Robert DuPont, Director of the National Institute on Drug Abuse when this monograph was published, states in his foreword, "This document represents a quantum advance in the Institute's heroin epidemiology efforts and reinforces the Task Force's prediction that we will experience another decade of significant breakthroughs in this vital area." The details of the epidemiology of a relatively rare event, such as heroin addiction, are unlikely to be of great interest to many psychiatrists. However, some of the information contained in this book is fascinating and will have an impact on both treatment approaches and public policy.

Using her data on servicemen involved with heroin use in Viet Nam, Robins emphasizes the instability of the heroin addict population over time. Her follow-up studies indicate that only 2.8% of regular heroin users in Viet Nam resumed regular use of heroin within 3 years of their return home. That important information has done much to discredit the old myth, "Once an addict, always an addict." In this context she comments, "We have increasing evidence that many heroin users never become addicted at all, and that many of those who do become addicted recover rather quickly without any medical treatment."

Despite the above information, it was surprising to see Hunt's estimate that there were 4,350,000 active heroin users in the United States in 1974. Using the same data as Hunt—from arrests, treatment programs, and urinalyses of prospective employees—O'Donnell calculated a range of 815,625 to 13,050,000. Obviously there are problems in current methods of estimating prevalence figures. Some credence is given to the higher figure by the fact that in a Bedford-Stuyvesant survey, 21% of the men aged 20 to 24 reported that they used heroin (p. 203). In Lukoff's view, prevalence figures of this magnitude make the libertarian approach to heroin use, exemplified by Szasz, less tenable. Such extensive use impairs the socialization of many young men as they prepare for adult roles and removes a significant segment of the population from "the creative work of the community."

In another chapter Sells examines the data obtained from treatment programs through the Drug Abuse Reporting Program (DARP), which examined 43,943 admissions over a 4-year period. Since 1969 heroin use by whites appears to be increasing and use by blacks decreasing. There also appears to be increased multiple drug use and use by adolescents. One-third of those who use heroin daily have no illegal sources of support and are not in trouble with the law when they enter treatment. The data also indicate that treatment helps control illicit drug use and reduces crime. An interesting footnote (p. 143) reports that in Detroit a 1% increase in treatment program enrollment was associated with a .23% decrease in property crime, while a 1% increase in the price of heroin was accompanied by a .16% rise in crime.

McGlothlin, using data from his follow-up study of the California Civil Addict Program, reports positive as well as negative consequences of the use of heroin. Heavy alcohol and other drug use is reduced during periods of regular heroin use. When using heroin daily, 20% of his subjects reported becoming intoxicated with alcohol 2 or more times a week. The proportion rose to 51% when heroin use stopped.

In her summary the editor reminds the other authors that "measurement, which is the starting point of epidemiologic research, requires exquisite clarity of definition, differentiation, and precision." Although the current state of the art is still far from this goal, much has been accomplished. One conclusion emerges from the work reported in this volume: heroin use is not a homogeneous phenomenon. The problem has a varying impact on different individuals and communities and requires multivariate responses.

JOHN N. CHAPPEL, M.D.
Reno, Nev.

Dimensions of Personality, *edited by Harvey London and John E. Exner, Jr. New York, N.Y., Wiley-Interscience (John Wiley & Sons), 1978, 599, pp., no price listed.*

This book consists of 13 chapters, each written at the request of the editors and devoted to research on a particular personality trait or dimension. It is a useful reference, bringing together in one place authoritative and generally well-written summaries of research on the major traits and providing, as was the editors' intent, "a sense of what has unfolded on the contemporary scene of personality research" (p. xv).

Each article begins with a discussion of the genesis of research on the trait under study and proceeds to a selective review of the experimental literature and to a summary. When possible, the scales that are used to measure the various traits are also included. It is interesting to note that clinical practice was the inspiration for only about half of the research described here (introversion-extroversion, trait anxiety, locus of control). Other concepts were developed during basic research in perception laboratories (field dependence-independence, repression-sensitization, sensation-

seeking) or were derived from the area of political science (authoritarianism, Machiavellianism).

For psychiatrists and psychiatric residents whose knowledge in the area of personality is largely theoretical, *Dimensions of Personality* can serve as an excellent and not overly technical introduction to experimental personality research, with only a few caveats. First, personality research is a diverse field, in which the study of variables of individual differences is only one major emphasis. Much personality research of interest to clinicians (e.g., in aggression, the emotions, sex roles, and attribution theory) is conducted under the banner of social psychology. Second, there is a great deal of controversy in the field of personality as to whether the trait approach represented in this book is the most fruitful or a major conceptual and methodological reorientation is needed. Even among those in favor of reorientation, disagreement as to the form it should take is widespread. Finally, Wilson's chapter on introversion-extroversion, although among the most clinically germane in the book, is misleading and biased. Its dismissal of psychoanalytic theory is not only arrogant but premature; the presentation of Eysenck's theory glosses over the extensive criticism that theory has provoked.

The research summarized in the individual chapters is impressive. Most of the concepts have been carefully defined and their utility in predicting and understanding particular domains of behavior well established. I was left, however, with an impression that the whole was somehow not equal to the sum of its parts. What is lacking in the book is what is lacking in personality research in general: a concern with synthesis and with the integration of disparate concepts through theorizing. Wittingly or not, the editors have created a book that depicts the current state of personality research in its structure as well as in its content.

PETER B. ZELDOW, PH.D.
Syracuse, N.Y.

Behavioral Treatment of Alcohol Problems, *by Mark B. Sobell and Linda C. Sobell. New York, N.Y., Plenum Press, 1978, 222 pp., $16.95.*

This book has been difficult to review because it concerns a critical analysis of the literature, arguments for and against, a complex research program, and a meticulous follow-up study regarding the feasibility of controlled nonproblem drinking as a goal of alcoholism therapy. The 1976 Rand report, Pattison's recent publications, and now the investigations of the Sobells take issue with the traditional belief that an alcoholic can never drink socially again. Obviously, there are a few alcoholics who regain control of their drinking, but whether this could ever be a safe or legitimate therapeutic goal is rather frightening to contemplate. I have had at least 15 patients who relapsed because of the Rand report. How many alcoholics read the Rand report and were able to resume nonproblem drinking is not known, so the concept of treatment directed toward changing pathological drinking into controlled drinking cannot be rejected out of hand.

The main body of this book is a report of a research project conducted at Patton State Hospital from 1969 to 1971. Individualized behavior therapy, consisting of electric shock avoidance, videotape replay, experimentally controlled consumption of alcohol, and individual therapy sessions directed toward problem-solving skills, especially the drinking problem, was given to 20 alcoholics w[illegible] achieving nonproblem drinking. Fourteen [illegible] were given the behavior therapy with the goal [illegible] and 36 subjects were not given the behavio[illegible] served as two control groups for both conti[illegible] and nondrinking comparisons.

An extensive and detailed monthly follow-[illegible] of 2 years was conducted on 69 of these 70 [illegible] results indicated that the behavior therapy g[illegible] attempting to learn nonproblem drinking beha[illegible] ter general outcome and longer periods of sob[illegible] behavior therapy group attempting abstinence[illegible] treated control groups. On the basis of these [illegible] thors imply that some alcoholics can be ta[illegible] their drinking to a nonproblem level. Who [illegible] might be or how many alcoholics would be su[illegible] unconventional treatment is not clear.

However, the authors suggest several [illegible] have found useful in predicting a successfu[illegible] ing outcome. These include a shorter drinking [illegible] arrests, fewer hospitalizations, a less im[illegible] stable personality, a less advanced or deteri[illegible] drinking, more resources and stronger suppo[illegible] higher intelligence. These characteristics w[illegible] apply to a better prognosis for any kind o[illegible] they are especially important if behavior t[illegible] goal of controlled drinking is attempted.

Certainly any therapist who has the [illegible] shape an alcoholic's drinking pattern to a n[illegible] could do well to read this book. The authors [illegible] their assessment, therapeutic, and evaluatio[illegible] sufficient detail to serve as a guideline in thi[illegible] troversial, method of treating alcoholism.

FREDERICK I[illegible]
S[illegible]

Alcoholism: A Comparison of Treatment and Study of the Influence of Marriage. Maudsley [illegible] *by Jim Orford, M.A., Dip. Psych., Ph.D.* [illegible] *wards, M.A., D.M., D.P.M. Oxford, Enstar* [illegible] *versity Press, 1978, 167 pp., no price listed*

This book is an expanded report of the re[illegible] wards presented at the National Council on [illegible] ference in Washington, D.C., in May 1976 [illegible] lished in the *Journal of Alcohol Studies* [illegible] marvelous example of the style of the sc[illegible] bane, diffident, examining many viewpoints [illegible] alternative hypotheses to counter his own [illegible] type of presentation lends itself to the reader [illegible] cepting some strong points of view that are [illegible] sented. Indeed, we could hope that more [illegible] would attempt to be as thorough and as cle[illegible] tion of their results and that they too would [illegible] ments such as this, which clearly dichotomi[illegible] ment variables while maintaining both respe[illegible] son as an individual and a clear scientific cl[illegible]

The research itself is a study in which [illegible] secutive randomized married alcoholic men [illegible] range alcoholism treatment of the kind consi[illegible] dard, and the other 50, after a thorough exp[illegible] that the responsibility for achieving the st[illegible] their own hands and could not be taken over [illegible] message was given in sympathetic and constr[illegible]

was explained that the husband would not be offered a further appointment at the clinic, but that the social worker would call each month to see the wife and collect news of her husband's progress.

The psychiatrist told both the treatment and the advice groups that the husband was suffering from alcoholism and advised that the treatment goal should be total abstinence, that the husband should continue or return to work, and that the husband and wife should attempt to make their marriage viable.

The results were startling over a 2-year follow-up in that there were no statistically significant differences in outcome between the treatment and the advice groups. Although they acknowledge that married alcoholics are a special classification, the authors suggest that perhaps long-stay inpatient treatment facilities are not as necessary as was once thought and that other provisions should be made for adopting, at least as a trial, the "advice" plan of management of the patient. Not a single man in the study was completely abstinent for the 2-year follow-up period.

An incidental but valuable aim of the study was the exploration of the alcoholic marriage by a number of observations and psychometric and historical explorations (of dominance-submissiveness, hostility, cohesion, and sexual activity, for instance). I would chide these alcoholism experts for pursuing their explorations in a vacuum that does not take into account the general psychiatric literature on marriage.

Of the marital variables studied, it was *cohesion* that most strongly related to outcome. Relatively cohesive couples were more than twice as likely to be in the good than in the bad outcome group at follow-up; relatively noncohesive couples were more than three times as likely to be in the "bad" group. The authors themselves point out the small number of couples involved and the need for replication.

The gnawing question that arises in the reader of alcohol literature is brought in by the relatively small degree of success (about one-third by their standards) that both treated and untreated clients achieved. There were also few men in the study who used Alcoholics Anonymous and who attributed any part of their success to AA. This contrasts with other follow-up statistics, e.g., those presented by the program of the U.S. Navy in which 84% of the patients over 25 years of age succeeded sufficiently to return to active duty (1).

I think we should not dismiss these discrepancies as being due to superior information gathering on the part of the Maudsley team. When we look at the two programs, we see other quite important variables that may influence results in such a complex field. The first, so well-known as to be banal, is the coercive value of a job-related referral to treatment (i.e., the Navy program). The second is more subtle, more open to scientific criticism, and yet a powerful force, i.e., the conviction on the part of those who provide treatment in the efficacy of a therapeutic mode. In the Navy program, the whole program is designed by people who believe absolutely that adaptation to the AA way of life is the single most important and necessary function to overcome alcoholism. In the Maudsley program, AA is one choice that is being studied, not advocated. Abstinence is another such variable. In fact, the "grapevine" in the London alcoholic community might be said to judge the Maudsley therapists justly or unjustly as leaning away both from abstinence and AA.

Under these circumstances I wonder if the lack of difference between outcomes of treatment and advice groups does not merely demonstrate the need for fervor on the part of those who provide treatment toward an outcome—a fervor that can be viewed by the client as ego supportive, motivating, and activating. Long stays in the Maudsley's neutral atmosphere made no difference, but there was not that much "business" to do. Long stays elsewhere might be valuable to overcome resistance to accepting a new way of life, to overcome suspicion and doubt of the "surrender" that AA demands, to openly accept the proferred "love" of the AA program, and to begin to see it and sobriety in practice.

The possibility of the efficacy of an "advice" strategy is in any case refreshing and supportive for many alcohol experts who only get one "chance at bat" with an alcoholic patient. I have seen many times the situation in which one extended and sympathetic interview with a patient or a patient and his or her spouse ending with clear recommendations has ushered in prolonged remission, either immediately or after an interval.

Dr. Edwards might take his own advice and look at the general psychiatric literature (2) in regard not only to marriage but to treatment. There is great interest in brief psychotherapy techniques—usually meaning a year and under for outpatient treatment—that call on the positive resources of the patient to actively seek improvement. It is my feeling that the exploration of such strategems in alcoholism as the "advice" group *can* lead to advances for some patients. However, a substantial and even major segment of the alcoholic population will still require inpatient indoctrination during which they learn about their disease and how to cope with it from those whose advice in imbued with fervor.

FRANK A. SEIXAS, M.D.
New York, N.Y.

The Care and Management of the Sick and Incompetent Physician, *by Robert C. Green, Jr., M.D., George J. Carroll, M.D., and William D. Buxton, M.D. Springfield, Ill., Charles C Thomas, 1978, 95 pp., $8.50.*

This small, timely book adds some much-needed hard data to the growing body of knowledge about physician illness. The experience of the Virginia State Board of Medicine provides the basis for these authors' study of the sick, incompetent, or unethical physician, and their conclusion is optimistic: well-considered intervention can effect a good prognosis. In addition to reviews of the serious subjects of drug addiction and alcoholism among physicians, the authors include chapters on maintaining professional competence by continuing education and on the subtle problems of aging. They point out that statistics about illness are still poor, that the profession as a whole still fails its sick members, and that adequate laws about reporting sick physicians are still needed. The medical profession must manage itself, or it will lose the right to do so. Our goal is to develop the most compassionate but effective ways of helping our sick colleagues, and these authors give us the benefit of their valuable experience.

ROBERT E. JONES, M.D.
Philadelphia, Pa.

The Childhood Emotional Pattern and Corey Jones: A Psychoanalytical Biography, *by Leon J. Saul, M.D. New York, N.Y., Van Nostrand Reinhold Co., 1977, 336 pp., $13.95.*

This book, which is Dr. Saul's tenth, is obviously intended to illustrate the time-honored insight expressed in conventional terms as "the child is father to the man" and in psychoanalytic theory by the genetic or developmental point of view. The metapsychology of psychoanalysis consists of the set of essential assumptions on which its theory is based. It includes five points of view: the dynamic, the economic, the structural, the genetic, and the adaptive. The genetic point of view is that psychological phenomena begin with inborn traits and develop according to an "epigenetic groundplan," that the early forms of any such phenomena remain potentially active, and that, as the individual's life goes on, those earlier forms heavily influence subsequent ones (1).

The format of the present work is the life history of one individual, ostensibly based on a partial psychoanalytic reconstruction. There is no discussion of theory or technique and no reference to the literature. As a child, Corey Jones was cherished by his mother, father, sister, and one of his aunts; throughout his life he expected to be loved unconditionally, and he was. The bulk of the book's content concerns his libidinal ties. His apparently successful, nearly painless progress from beloved child to inhibited young adult to potent, successful lover and husband evokes Anna Freud's concept of normal developmental lines (2).

In fact, the book serves as an example of an aspect of the genetic point of view in psychoanalytic metapsychology that has recently been addressed by Abrams (3). He pointed out that the genetic basic assumptions include developmental propositions that tend to be overlooked in clinical work in favor of the emphasis on "antecedent determinism." In other words, there is an emphasis on determinism as opposed to "transformational processes" in development. Abrams has stated that we tend to confuse the genetic *point of view* with the genetic *approach*, which involves searching for antecedent causes in clinical psychoanalysis (3).

The transformational view of development is a reflection of the progressive (or regressive) potential in the human organism, and so it takes into account individuals' biological endowment (e.g., intellectual) as well as the effects of the process of growth and maturation on the outcome of personality formation.

Cases of the Reincarnation Type, Vol. II: Ten Cases in Sri Lanka, *by Ian Stevenson, M.D. Charlottesville, Va., University Press of Virginia, 1978, 367 pp., $20.00.*

In reviewing an esoteric treatise of this kind, one must consider the integrity of the author as well as the nature of the subject. In this case the author demonstrates an admirable ability to treat a controversial subject in a controversial way. There is a difference. Controversy has a connotation implying polemics, disputation, and [illegible] novation has a positive connotation implying introduction of new ideas, renovation of old ideas, horizons, and breaking new ground. Dr. Stevenson, Professor of Psychiatry in the Division of Parapsychology, University of Virginia, clearly belongs in the [illegible] He therefore deserves our respectful attention and qualified agreement. It has been my personal [illegible] our profession welcomes innovative projects [illegible] are presented in a conservative, ethical, and [illegible] ner.

A mind without curiosity, it is said, is like [illegible] without a telescope. This book on reincarnation [illegible] ly stimulate such curiosity. For those readers [illegible] victims of the tenacity of tradition, it will be a [illegible] road to discovery, a source of intellectual [illegible] incentive to grant a latitude of opinion not [illegible] in precise science.

Despite the preposterous claims of certain [illegible] for hypnotic "regression," and despite the [illegible] that examples of reincarnation are most often [illegible] adherents of religions rooted in that belief [illegible] Buddhism in Stevenson's cases), certain [illegible] have rendered reincarnation a bit more scientifically [illegible] able if not yet scientifically proven. I refer [illegible] "immortality" of the germ plasm and its genetic [illegible] the provocative allegation, recently revived by [illegible] lian photography, that energy fields (auras, etc.) [illegible] may survive physical death, may retain elements [illegible] sciousness, may interact and reunite with [illegible] ent, and future energy fields, and may even [illegible] soul and spirit (1). It therefore seems not [illegible] suggest that reincarnation should not be ignored [illegible] not believed.

In this book we have a dispassionate, painstaking [illegible] cinating account by a respected psychiatrist [illegible] garded in parapsychological circles as a "[illegible] in the field. Of particular interest to psychiatrists [illegible] venson's suggestion that certain skills, phobias [illegible] behavior, confusion of gender identity, allergies [illegible] physical abnormalities may be related to [illegible] events in previous lives.

In addition to the 10 cases that make up the [illegible] book, the author includes an informative discussion [illegible] the Sinhalese belief in reincarnation and a glossary [illegible] and cultural terms essential to an understanding [illegible] veda Buddhism in the context of the case reports. Stevenson has written many articles on the subject [illegible] tion, and the present volume is an extension [illegible] 3). Interested researchers, as well as the general [illegible] look forward with interest and edification to [illegible] investigations and reports.

STANLEY R. [illegible]

Mental Health in the Metropolis: The Midtown Manhattan Study, Book Two, revised, *by Leo Srole, Thomas S. Langner, Stanley T. Michael, Price Kirkpatrick, Marvin L. Opler, and Thomas A.C. Rennie; edited by Leo Srole and Anita Kassen Fischer. New York, N.Y., Harper Torchbooks (Harper & Row), 1977, 546 pp., $6.95 (paper).*

Books one and two of *Mental Health in the Metropolis* were originally published as volume 1 of the Midtown Manhattan Study (1). Dr. Srole has added new material, including four new chapters and two appendixes in book two and a new introduction in book one.

A pioneer work when it first appeared (1, 2) and now a classic of its genre, the Midtown Manhattan Study is a model for the collaboration of sociology and psychiatry. It is dedicated to the memory of Dr. Thomas Rennie, the founder and first director of the Midtown Manhattan Mental Health Study. Dr. Srole writes more like a novelist than a sociologist, and he refers to the great social realists and psychological novelists—Zola, Proust, Joyce, and Bellow.

Book one of the paperback version of the study, which is briefly summarized in book two, described the "psychosocial instruments" used in what the authors call their "exploratory surgery." Data comparing the Midtown Manhattan population with other general populations and findings on Manhattan's prime-of-life age groups, its men and women, and the various stages of marital status they represent are included.

Book two carries the study into the community. It cites home survey samples and compares rich, middle-class, and poor socioeconomic groups; immigrants and native-born groups; and the many national, ethnic, and religious groups—all in relation to mental health findings. It also discusses the metropolis versus the small town and the country and their respective "health-linked" qualities as human habitats. The documentation is extensive, and the charts are easy to read. References abound to the authors' predecessors, the Lynds (3), Warner and Low (4), Hollingshead and Redlich (5), and more contemporary workers such as Kenneth Kenniston.

A sample of just a few of the salient findings of this study should whet one's appetite for reading the entire work. Familiar now is the statement that the frequency of mental health impairment varies inversely with socioeconomic status. Using the four categories of well, mild symptom formation, moderate symptom formation, and impaired, the authors found that 34% of young people aged 20–29 whose parents were in the upper socioeconomic classes were well, compared with 21% of those whose parents were in the middle classes and only 13% of those whose parents were in the lower classes. Although the percentages were closer together at the impaired level, only 10% of the upper-class youth, compared with 17% of the middle class and 20% of the lower class, were judged severely impaired.

It was the large number of individuals found in the home survey samples who had symptoms of psychiatric illness that was so shocking when the study appeared 15 years ago, and it is still shocking. Whether or not poverty and other deprivations of socioeconomic origin have a profound effect on mental health is still being debated, but the studies of Srole and associates as well as the subsequent studies they have inspired remain as solid evidence.

An issue that Srole calls an ancient bias is the Rousseau-Jefferson idea that a big city like New York is "a cloacina of all the depravities of human nature." Srole brings us up to date on this issue in a chapter on the economic crisis of New York in 1975 and the anti-urban feeling of politicians, poets, and even sociologists (especially the "Chicago school," where Srole trained). Srole states that these groups are misled by nostalgic idealization of what Marcel Proust called "remembrance of things past." Srole cites Benjamin Rush, who said that cities are "pesilential to the morals, health and liberties of man." He then provides figures showing that although people living in the country lived longer than people in the city before the twentieth century, in 1960 the difference between city and country was insignificant. The Midtown Manhattan Study itself was used as evidence of the pathological environmental stress of the big city because of the large percentage of mentally ill people found in the home surveys. However, a parallel study of Stirling County in rural Nova Scotia, Canada (5), found that "half of the adults in Stirling County are *currently* [author's italics] suffering from some psychiatric disorder as defined by the American Psychiatric Association's Diagnostic and Statistical Manual (1952)." Srole also found that a New Zealand study showed that the psychotropic drug prescription rate per capita varied inversely with the size of the biggest cities.

As summary Dr. Srole offers "post hoc hypotheses" regarding the sociocultural factors that affect mental health adversely. First are the "multiple interwoven deprivations" imposed on children of indigent parents. Second are the "stigmatize-rejection mechanisms" rooted in society's rewarding and penalizing system for prestige or the lack of it. These are most extreme for blacks, but the poor, disabled, elderly, and nonmainstream population groups are also demeaned, and their self-esteem suffers. Third is the role of transition states such as disastrous life events.

The basic formulation of the authors is the following:

> Mental morbidity is in part an immediate manifestation of an impaired ego, damaged by an earlier malfunctioning family structure that, in turn, had been rendered defective, at least partially, by disruptive intrusions from, or defaults by mainstream community and national social networks.

We now call this phenomenon the biopsychosocial hypothesis of mental illness.

Finally, Dr. Srole answers some critics of the original work, proposes new research, and states that he is currently working on a restudy to check on the changes that have occurred since 1954. This classic work should be included in every residency training program as required reading. It is highly recommended to psychiatrists of all persuasions, including not only those who are more biologically grounded but also those who are more psychoanalytically oriented. The work provides a bridge between these groups.

JOEL S. HANDLER, M.D.
Chicago, Ill.

Handbook of Rational-Emotive Therapy, *by Albert Ellis and Russell Grieger. New York, N.Y., Springer Publishing Co., 1977, 433 pp., $22.50; $14.95 (paper).*

Although I was aware of Albert Ellis' reputation as a popular psychologist with a proclivity for placing his views before the general American public, I was unaware that he considered himself the founder of rational-emotive therapy, an approach to therapy that he views as unique and very much his discovery. I was furthermore unprepared for a style of presentation that is, at best, jaunty and unprofessional in tone and, at worst, disrespectful and ignorant, particularly regarding psychoanalysis and analytic psychotherapies, which are persistently harshly attacked. This is particularly ironic because it seems to me that rational-emotive therapy is derivative from dynamic forms of psychotherapy, representing the isolation and selection of one aspect of all effective psychotherapy rather than an original school of psychotherapy.

I do not wish in this review to appear as a defender of classical psychoanalysis as the exclusive source of effective psychotherapy. It seems important to me, however, to stress how often Ellis attributes a particular position or limitation in treatment technique to psychoanalysis when it is not in fact an aspect of psychoanalytic technique or theory. He then proceeds to present his "liberated" view as a welcome contrast. Although there is considerable room for disagreement within psychiatry, especially with regard to the practice of dynamic psychotherapy, there is no doubt that reading this handbook would bring all of us with a dynamic orientation closer together. Besides being out of touch with anything vaguely analytic that has occurred since 1910, Ellis and most of the other contributors to this book seem to have little knowledge of the general psychiatry literature.

Ellis as a writer is exceedingly self-indulgent. To illustrate, I quote, "Even the redoubtable Sigmund Freud occasionally saw fit to note, before he became anally fixated on the notion of having to bugger his mother, that emotional disturbance arises from what he called ideogenic sources, meaning from nutty and highly exaggerated ideas." This represents only the tip of the iceberg, stylistically speaking. In what may be one of the more offensive chapters in this rather astounding book, Ellis finds women frequently guilty of "love slobbism" and proceeds in what is a profoundly male chauvinistic way to devalue women's wishes for reliable dependency relationships in the interpersonal sphere.

If one is able to overcome Ellis' stylistic atrocities (it should be noted that chapters by other contributors are of a somewhat less offensive nature), one is still faced with the need for evaluating a questionable and superficial approach to psychotherapy. Unfortunately, Ellis and the other contributors continually point to increased symptomatic improvement as proof of the greater effectiveness of rational-emotive therapy as compared with other forms of psychotherapeutic treatment. Their naïveté in this regard is startling. The ability to alter subjective states of well-being by suggestion has been well established. Furthermore, modern dynamically oriented psychiatrists are aware that a variety of therapeutic techniques, ranging from anal[illegible] psychotherapy and from drugs to other s[illegible] ventions, may be successful in interrupting be[illegible] major illnesses.

I think it is of some importance, after stating [illegible] reservations about the quality of the book, to cl[illegible] authors mean by rational-emotive therapy. [illegible] easy task, as anyone inclined to read the book [illegible] soon find out. Perhaps the best summary com[illegible] himself:

> Given the position that people create their [illegible] ieties, guilts, depressions and angers, by the [illegible] beliefs they hold, the goal of therapy is to [illegible] client to give up these beliefs as well as the s[illegible] behaviors that often accompany them and to [illegible] their rational thinking and believing. [illegible] context of a direct verbally active and didac[illegible] the rational-emotive therapist makes full [illegible] Socratic method of disputing the client's [illegible] liefs in order to get him or her first to reco[illegible] then think them through, and finally reline[illegible] The therapist repeatedly and vigorously [illegible] clients think about their beliefs and insists [illegible] fer evidence to prove the things they have f[illegible] ply accepted.

Since most interpersonal or dynamic psychoth[illegible] reducing the influence of irrational beliefs, it is [illegible] what makes Ellis insist that he has discovered [illegible] ment entity.

As far as I can ascertain, the therapist's sta[illegible] emotive therapy is hostile toward the patient's [illegible] though all therapists often find it necessary to l[illegible] tively healthy neurotic patients to tolerate t[illegible] while treatment continues or to refrain from [illegible] peating a complaint in the service of continued [illegible] not think that the position of pitting oneself ag[illegible] tional in the patient is particularly helpful or just[illegible] unacceptable, however, is Ellis' disparaging at[illegible] the influence of the past relationships with pr[illegible] and about the importance of the transference [illegible] scious and symbolic meanings in the patient's [illegible] bal associations, and responses to the therapis[illegible] well-established aspects of dynamically orien[illegible] therapy are dismissed. I stress this fact becau[illegible] that there is some need for increased emphas[illegible] difficulties in the cognitive sphere. There may [illegible] tients whose treatment should be kept at a mor[illegible] level and for whom correction of educational [illegible] constricted world views, and a tendency to [illegible] tantly irrational ideas need to be addressed in [illegible] py. What is unsettling is to find a system [illegible] therapeutic thought that denies unconscious er[illegible] tors linked to the primary object relationship[illegible] the more superficial, cognitive difficulties.

Certainly naïveté is no crime. All of us w[illegible] psychiatric fields have areas of limitation in kn[illegible] this is different from elevating areas of limita[illegible] position of an asset, as Ellis tends to do. Fu[illegible] clinical example after clinical example, one get[illegible] sion of patients being assaulted by Ellis' pa[illegible] view, which appears to be harsh, hedonistic, an[illegible] For example, Ellis often shows patients that [illegible] ternal event that is causing a reaction but inte[illegible] tional thoughts. This results, at the clinical lev[illegible]

couraging patients to accept or ignore inconsiderate and abusive behavior by their friends or spouses. For Ellis it is the patient's assumptions that are the problem, i.e., assumptions that they should be treated well or that things should go right for them in life.

Working consistently with patients to help them reconstruct their histories and connect the past with the present, the unconscious with the conscious, is at the core of all dynamic psychotherapies. Part of this work includes attention to irrational ideas and attitudes. Unfortunately, this volume is written in such a way as to preclude its being a significant study of irrational ideas and how they can be managed in psychotherapy.

HENRY J. FRIEDMAN, M.D.
Boston, Mass.

Clinical Quantitative Methods, *by Richard W.J. Neufeld, M.D. New York, N.Y., Grune & Stratton, 1977, 184 pp., $14.50.*

What might be the goals of a statistical book for the use of psychiatrists? Initially, one would want help with understanding a literature that is becoming increasingly statistically complex, not only for the reader but also for the journal reviewer. Journal reviewers seem to need more and more help in understanding statistics, and frequently they need more help than they manage to get. A book that would serve this purpose would, on a very simple level, explain the purpose of a test, with examples from the clinical literature and various types of interpretations.

A second goal would be to show simple statistical designs for use in a case report with multiple quantitative observations or in small-sample research. This would aid the psychiatrist preparing something he or she finds interesting for the literature. Such a book in the nonparametric area is that of Siegel (1), which gives clear examples as well as purposes and methods of calculation and interpretation.

Finally, a third purpose of a statistics book for psychiatrists would be to provide a comprehensive resource in the field such as Winer's work (2). This would be used by the more sophisticated statistical researcher in checking assumptions, appropriate designs, statistics, and methodological procedures.

Clinical Quantitative Methods attacks the problem of single case design. Neufeld's approaches are not simple and therefore not of use to the ordinary psychiatrist. He does not cite some of the major works in this area. The common simple statistical procedures of chi square, t tests, and correlations are not presented. The areas that Neufeld does use to help readers and reviewers understand an increasingly complex literature are varied. He uses examples from such areas of interest to psychiatrists as schizophrenia and therapy evaluation as well as depression and evaluation of symptoms. Only a minority of the examples are from areas of somewhat less interest to the general psychiatrist. However, his examples are more complex than can be understood by the psychiatrist with a minimal background in statistics. Although journal reviewers seem to be more sophisticated in statistics than the average psychiatrist, I would doubt that many of them would be able to follow the procedures in this book if they were presented with a paper for evaluation.

Finally, Neufeld at no point attempts to present his book as a comprehensive reference book. This is wise, except that the title, *Clinical Quantitative Methods*, does not have a subtitle or suggest the area covered by the book. The introduction suggests that the emphasis is on the clinical part of the title and that some potentially useful areas of statistical analysis are presented. Again, however, it is not a comprehensive discussion of this area, nor does Neufeld attempt to point to other areas or books that might be useful to the person attempting to analyze data on patients or designing a study of clinical procedures or evaluation.

DANIEL S.P. SCHUBERT, M.D., PH.D.
Cleveland, Ohio

The Alcoholic Marriage: Alternative Perspectives, *by Thomas J. Paolino, Jr., M.D., and Barbara S. McCrady, Ph.D. New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1977, 200 pp., $14.50.*

The authors state that this book was written because of their strong opinion that regardless of the theoretical perspective from which the alcoholic is conceptualized, his or her drinking and his or her marriage are inseparably related. With this as their objective, the authors examine the marriage of the alcoholic from four points of view: psychoanalytic, sociological, behavioral, and systems theory. Each perspective is reviewed in separate chapters on the basis of empirical evidence supporting or challenging the position in question. The chapters are divided by subtitles into topical components that offer a helpful outline to guide the reader through the authors' encyclopedic summation.

The writers offer their impression "based on the research evidence reviewed, that the behavioral perspective offers some of the most promising concepts and techniques developed to date." At the same time, they see the systems, psychoanalytic, and sociological concepts as offering ideas for the enrichment of treatment that would not be suggested by a strictly behavioral viewpoint.

As the basis of their extensive review of the literature, generously and selectively referenced in each chapter, the authors offer arguments that present a formidable challenge to the idea that people who are married to alcoholics tend to be psychologically disturbed. At the same time, they attempt to demonstrate how psychoanalytic theory has been "inadvertently abused, resulting in oversimplified theories about the alcoholic marriage." How well they may have succeeded in substantiating their position would appear to depend, to a considerable extent, on the professional sophistication of the reader.

The last section of the book, Treatment Implications, focuses on aspects pertaining to entering treatment and motivation for treatment, assessment of the alcoholic marriage, the delivery of treatment, and the therapeutic relationship. This section is worthy of perusal by sophisticate and novice seeking to come to therapeutic grips with the role of the spouse in the treatment course of alcoholics.

All in all, the authors present a virtuoso performance in their assessment of the four models of human behavior as applied to any aspect of normal or abnormal behavior. How-

ever, their exposition suffers from an important omission in that they fail to take advantage of their survey to comment on the possible extent to which the application of the different models might worsen the relationship between patient and spouse, even though such studied comments would at best yield only rough approximations. The book is thoughtful and does not make for easy reading. For those seriously concerned with psychiatric treatment, its reading and rereading should be rewarding because it offers a helpful guide in an area beset with complexities. I can recommend this book as a useful addition to one's working library.

ALBERT A. KURLAND, M.D.
Baltimore, Md.

Psychological Disorders of Children: A Handbook for Primary Care Physicians, *by Mark A. Stewart, M.D., and Ann Gath, D.M. Baltimore, Md., Williams & Wilkins Co., 1978, 160 pp., $9.95 (paper).*

Pedagogy is becoming a demanding taskmaster because of the current profusion of facts and varying clinical experiences. Selection of content has become as important as the manner of transmission. How should the old and new formulations of behavioral disturbances be correlated with each other? Can theory and practice drawn from experiences with adult disturbances be applied to children? Can the traditional medical model be made to fit the problems of children? Can theoretical sectarianism be avoided? Can psychological and biological determinants be integrated in a reasonable form of data selection and presentation? All of these questions are correctly raised in the short preface of this small book. Regrettably, the attempt to respond to these issues falls short of the intent of the authors to respond to them.

This book is presented as a handbook for primary care physicians, whom the authors identify as residents in psychiatry, pediatrics, and family practice, nurse practitioners, psychiatric nurses, medical students, and students in clinical psychology and other fields. In the face of their selection of so broad an audience, the authors assume a weighty responsibility to carefully choose, qualify, and quantify their subject matter. Nowhere do they meet this responsibility.

In their opening chapter, they question the validity of diagnosis in child psychiatry and then proceed to construct a book based on the specificity of diagnostic entities. In their next chapter, on infantile autism and schizophrenia, they devote 12 pages to infantile autism and dismiss the subject of childhood schizophrenia with less than 2 pages, which begin with the amazing statement that "true schizophrenia is probably rarer in children than autism." They justify this statement by quoting the isolated work of Makita reported in 1966 in the *Folia Psychiatrica et Neurologica Japonica* but completely ignore the vast literature on childhood schizophrenia in other major psychiatric publications. Anyone familiar with the complexity of the subject of infantile autism will be distressed both by the content and documentation of this section.

Uneven selection and presentation dominate the remaining chapters of the book. Nearly all of the sections reflect a combination of diverse bits of clinical work linked together by the authors' choice or inference. The result is a lack of clarity and the violation of stated purpose. The book does not achieve its goal of being "a handy introduction to child psychiatry," nor does it respond to the many questions raised in its own preface. In fact, this book [illegible] very questions it professes to answer. Its [illegible] from diagnostic entities to presentations of [illegible] tions. Conflicting attitudes between psycho[illegible] logical determinants are resolved by ignoring [illegible] of an extensive body of literature—usually in [illegible] cal area. Rarely do the authors point out [illegible] component to a physiological disturbance. [illegible] a simplistic representation of complex issues.

SOL NICH[illegible] M.D.
Ve[illegible] N.Y.

Children of Parting Parents, *by Lora Heims[illegible] New York, N.Y., Jason Aronson, 1978, 59[illegible] ed.*

The author is a clinical psychologist who [illegible] the staff of the MIT Psychiatric Service, Cam[illegible] and the Judge Baker Guidance Center in Bos[illegible] in the private practice of psychotherapy [illegible] adults. She reports material from more than [illegible] their parents whose problems had arisen [illegible] divorce, or death, with resulting emotional [illegible] children.

The book is divided into three sections. In [illegible] the author presents a wide range of underly[illegible] material presented reports on changing interact[illegible] men and women, changing attitudes toward c[illegible] changing role of the family in history, and cha[illegible] gy and in customs concerning marriage, div[illegible] care. In this first section the author describes [illegible] theories with reference to identification proc[illegible] ports on the various aspects of grief in childh[illegible] lescence.

In the second section of this book Dr. Tess[illegible] siderable clinical material, ranging from sing[illegible] therapy of several years' duration. In the th[illegible] author reports in detail about the therapy pro[illegible] suggestions not only for parents and profes[illegible] others in the child's social milieu.

The clinical material reveals clearly the au[illegible] sitivity, and professional competence. She [illegible] painful countertransference reactions that [illegible] dealing with grieving children and their paren[illegible] rich in clinical material. The case reports in[illegible] the material presented by the children, pare[illegible] parents but also the author's verbal responses [illegible] viduals, including her questions and interpret[illegible]

This book has an extensive bibliography [illegible] theoretical and clinical contributions. The pu[illegible] book at this time is of significance because [illegible] creasing rate of divorce, custody battles, [illegible] Many other writers have emphasized the se[illegible] traumata suffered by children and their paren[illegible] of divorce and remarriage. Dr. Tessman's [illegible] gives ample documentation to the needs of s[illegible] for professional guidance during and after [illegible] death of one parent. This book is highly rec[illegible] those in the mental health profession who de[illegible] who have lost a parent by divorce or death.
